Methylquinidine, $C_{20}H_{23}N_2O_2Me$, is obtained when the methiodide is boiled with an alkali; it is a yellow oil, readily soluble in ether, chloroform, benzene, and dilute acids. *Ethylquinidine*, $C_{20}H_{23}N_2O_2Et$, prepared in like manner, is a yellow oil.

Quinidine benzyl chloride, $C_{20}H_{24}N_2O_2,C_7H_7Cl$, is a colourless, vitreous compound, melts at 190—195°, and is readily soluble in water and alcohol; its *platinochloride*, $C_{27}H_{31}N_2O_2,HCl,PtCl_4$, is a yellowish-red, crystalline powder.

Quinidine dimethiodide, $C_{20}H_{24}N_2O_2,2MeI + 1\frac{1}{2}H_2O$, crystallises in lemon-yellow, seemingly rhombic plates, loses its water at 130°, begins to decompose at 148°, and melts at 156°; it is more readily soluble in water, but more sparingly in alcohol than the methiodide. The *diethiodide*, $C_{20}H_{24}N_2O_2,2EtI$, crystallises in reddish-yellow prisms with $1\frac{1}{2}$ mols. H_2O or in light yellow plates with 1 mol. H_2O; it begins to decompose at about 170°, melts at 205°, and is very readily soluble in hot water, but much more sparingly in alcohol.

Quinidine diethyl nitrate, $C_{90}H_{24}N_2O_2,2EtNO_3 + H_2O$, prepared by warming an aqueous solution of the diethiodide with silver nitrate, crystallises in large, transparent prisms, loses its water over sulphuric acid, and melts at 91° with decomposition. The corresponding *sulphate*, $C_{20}H_{24}N_2O_2,Et_2SO_4$, is a brown syrup.

Ethylchitenidine, $C_{19}H_{21}EtN_2O_4$, can be obtained by oxidising quinidineethylammonium hydroxide with potassium permanganate in the cold; it crystallises in well-defined, yellowish prisms containing 3 to 4 mols. H_2O, loses its water at 100°, melts at 287°, and is readily soluble in hot water, dilute alcohol, acids, and dilute alkalis, but insoluble in ether. The *platinochloride*, $C_{19}H_{21}EtN_2O_4,H_2PtCl_6$, is a yellow, crystalline compound, and seems to contain 2 mols. H_2O. The *sulphate*, $C_{19}H_{21}EtN_2O_4,H_2SO_4$, crystallises in small prisms, and melts at 218° with decomposition.

Benzyldihydroxycinchotenine, $C_{18}H_{19}N_2O_5{\cdot}C_7H_7$, is formed when cinchonine benzyl chloride is oxidised with potassium permanganate in the cold. It crystallises in slender, colourless needles, melts at 278° with decomposition, and is almost insoluble in water, cold alcohol, ether, and chloroform, but soluble in hot alcohol and acids. The *hydrochloride*, $C_{25}H_{26}N_2O_5,2HCl + H_2O$, crystallises from hot water in lustrous, efflorescent needles. The *platinochloride*, $C_{25}H_{26}N_2O_5,H_2PtCl_6$, separates from hot alcohol in yellowish-red crystals, melts at 290—291° with decomposition, and is insoluble in water. The *mercurochloride*, $C_{25}H_{26}N_2O_5,H_2HgCl_4$, forms small, colourless needles. The *sulphate*, $C_{25}H_{26}N_2O_5,H_2SO_4$, separates from dilute alcohol in lustrous, efflorescent needles. The *nitrate*, $C_{25}H_{26}N_2O_5,HNO_3 + 2H_2O$, crystallises in needles, loses its water at 100°, and melts at 178°. The *dimethiodide*, $C_{25}H_{26}N_2O_5,2MeI$, crystallises from alcohol in yellow needles, and melts at 205° with decomposition; it separates from water in yellowish-brown, prismatic crystals which contain $3\frac{1}{2}$ mols. H_2O, and melt at 198° with decomposition. The *dimethobromide*,

$$C_{25}H_{26}N_2O_5,2MeBr,$$

forms yellow needles, melts at 210° with decomposition, and dissolves freely in water and alcohol.

Benzyldihydroxycinchotenidine, $C_{18}H_{19}N_2O_5{\cdot}C_7H_7$, can be obtained by oxidising cinchonidine benzyl chloride with potassium permanganate. It crystallises in slender, colourless needles, melts at 248°, and is readily soluble in hot alcohol and dilute acids, but only very sparingly in hot water, and insoluble in ether and chloroform. The *platinochloride*, $C_{25}H_{26}N_2O_5,H_2PtCl_6$, is a heavy, yellow, crystalline powder. The *mercurochloride*, $C_{25}H_{26}N_2O_5,H_2HgCl_4$, separates from hot alcohol in slender, colourless needles.

Cinchonidine benzyl chloride, $C_{19}H_{22}N_2O,C_7H_7Cl + H_2O$, crystallises from water in large octahedra, loses its water at 100°, and melts at 198° with decomposition; it is only very sparingly soluble in cold water, but dissolves freely in alcohol, acids, and hot water. The *platinochloride*, $C_{26}H_{29}N_2ClO,HCl,PtCl_4 + H_2O$, is a yellow, crystalline powder insoluble in water and alcohol. The *mercurochloride*, $C_{26}H_{29}N_2ClO,HCl,HgCl_2$, crystallises from boiling alcohol in lustrous needles, and is only sparingly soluble in cold water.

Benylcinchonidine, $C_{19}H_{21}N_2O{\cdot}C_7H_7$, prepared by treating the preceding compound with potash, is a yellow oil. The *platinochloride*, $C_{26}H_{28}N_2O,H_2PtCl_6 + 3H_2O$, is a yellow, crystalline compound, and loses its water at 110°.

The following experiments show that when cinchonidine is caused to combine both with 1 mol. of methyl iodide and 1 mol. of ethyl iodide, the properties of the final product are dependent on the order in which combination has taken place.

Cinchonidine methiodide hydriodide, $C_{19}H_{22}N_2O,MeI,HI + H_2O$, is obtained by the action of ethyl iodide on cinchonidine methiodide in alcoholic solution; it crystallises from water in pale yellow, monosymmetric prisms, $a : b : c = 0{\cdot}3440 : 1 : 0{\cdot}3048$, $\beta = 77°\ 57'$, loses its water at 105°, and melts at 240—242° with decomposition.

Cinchonidine dimethiodide, $C_{19}H_{22}N_2O,2MeI + 2H_2O$, crystallises from water in reddish, rhombic prisms, $a : b : c = 0{\cdot}5033 : 1 : 0{\cdot}3140$.

Cinchonidine methiodide ethiodide, $C_{19}H_{22}N_2O,MeI,EtI + 2H_2O$, prepared by heating the methiodide with ethyl iodide in alcoholic solution at 120—150°, separates from water and from alcohol in reddish-yellow, rhombic crystals, $a : b : c = 0{\cdot}6992 : 1 : 0{\cdot}9662$, loses its water at 105°, and melts at 243—245° with decomposition.

Cinchonidine ethiodide hydriodide, $C_{19}H_{22}N_2O,EtI,HI + H_2O$, forms monosymmetric crystals, $a : b : c = 1{\cdot}0849 : 1 : 1{\cdot}6775$, $\beta = 78°\ 39'$, loses its water at about 105°, and melts at 225° with previous decomposition.

Cinchonidine ethiodide methiodide, $C_{19}H_{22}N_2O,EtI,MeI$, prepared by treating the ethiodide with methyl iodide, forms yellow, monosymmetric crystals, $a : b : c = 1{\cdot}6304 : 1 : 1{\cdot}0190$, $\beta = 81°\ 39'$, and melts at 255° with decomposition.

Cinchonidine diethiodide, $C_{19}H_{22}N_2O,2EtI$, forms anhydrous, rhombic plates, $a : b : c = 1{\cdot}5527 : 1 : 1{\cdot}0408$, and long, rhombic prisms, $a : b : c = 0{\cdot}7341 : 1 : 0{\cdot}9557$, which contain 2 mols. H_2O.

Cinchonine ethocyanide, $C_{19}H_{22}N_2O,EtCN$, prepared by treating cinchonine ethyl sulphate with barium cyanide, crystallises in colourless needles or prisms, melts at 160—165° with decomposition, and is readily soluble in water and alcohol, but insoluble in ether.

A compound of the composition $C_{19}H_{22}N_2O,EtI,Hg(CN)_2$ is precipitated in colourless crystals when a solution of cinchonine ethyl iodide is treated with mercuric cyanide; it melts at 210° with decomposition, and is soluble in hot water and alcohol, but insoluble in ether. The corresponding *bromide*, $C_{19}H_{22}N_2O,EtBr,Hg(CN)_2$, crystallises from alcohol in colourless needles, melts at 200° with decomposition, and is soluble in boiling water. The compound of the composition $C_{19}H_{22}N_2O,C_7H_7Cl,Hg(CN)_2$ crystallises from alcohol in colourless prisms, and melts at 220° with decomposition.

A compound of the composition $C_{19}H_{22}N_2O,EtI,AgCN$ is formed when cinchonine ethiodide is treated with silver cyanide; it crystallises in needles, and melts at 195°. The corresponding *bromide*, $C_{19}H_{22}N_2O,EtBr,AgCN$, forms small, colourless needles, and melts at 194° with decomposition.

Cinchonine diethyl nitrate, $C_{19}H_{22}N_2O,2EtNO_3$, prepared by decomposing the diethiodide with silver nitrate, crystallises from water in transparent plates, and melts at 245° with decomposition. The corresponding *sulphate*, $C_{19}H_{22}N_2O,Et_2SO_4 + 2H_2O$, forms yellowish needles, and melts at 208° with decomposition. The corresponding *chloride*, $C_{19}H_{22}N_2O,2EtCl + 2H_2O$, is a crystalline, hygroscopic compound, and melts at 205° with decomposition.

A compound of the composition $C_{19}H_{22}N_2O,2EtI,2Hg(CN)_2$ is formed when a concentrated solution of cinchonine diethiodide is treated with mercuric cyanide; it separates from boiling alcohol as a powder, begins to decompose at 120°, and melts at 155°. The corresponding *bromide*, $C_{19}H_{22}N_2O,2EtBr,2Hg(CN)_2$, is a colourless, crystalline powder, and melts at 180° with decomposition.

The above experiments, and the results of a comparative study of the alkyl halogen additive products of isoquinoline, pyridine, and the cinchona alkaloïds which the author and his pupils have previously published, lead to the conclusion that in the cinchona alkaloïds the nitrogen atom with which the first added alkyl halogen molecule combines is analogous in function, and is combined in the same way as the nitrogen atoms in isoquinoline and in pyridine respectively; the nitrogen atom with which the second added alkyl halogen molecule combines has, on the other hand, the same function as the nitrogen atom in quinoline.

Diethylidenecinchonine, $C_{23}H_{30}N_2O$, is obtained by treating the dialkyl halogen additive products of cinchonine with moderately concentrated alkalis; it is a yellow powder, melts at about 85°, turns red on exposure to the air, and is very readily soluble in alcohol and dilute acids, but only sparingly in water. The *platinochloride* $C_{23}H_{30}N_2O,H_2PtCl_6$ is a yellow, crystalline powder. The *ethobromide* $C_{23}H_{30}N_2O,EtBr$, obtained by heating the base with ethyl bromide at 100°, is a reddish-brown, amorphous substance. The *methiodide*, $C_{23}H_{30}N_2O,MeI$, is a yellowish-red powder, soluble in water and alcohol.

Triethylidenecinchonine, $C_{25}H_{34}N_2O$, is formed when the ethobromide just described is boiled for a long time with potash; it is a reddish-brown, resinous substance.

Diethylidenecinchoxine, $(C_{23}H_{30}N_2O)_2O$, is formed when diethylidene-

cinchonine undergoes oxidation by exposure to the air; it is a dark-red powder, melts at 95°, and dissolves freely in dilute acids. The *platinochloride*, $(C_{23}H_{30}N_2O)_2O,H_2PtCl_6$, is a heavy, reddish-yellow powder. The *ethobromide*, $(C_{23}H_{30}N_2O)_2O,2EtBr$, is a brown syrup.

F. S. K.

Bases Homologous with Quinine. By E. Grimaux and A. Arnaud (*Compt. rend.*, **114**, 672—673).—Cupreïne, $C_{19}H_{21}N_2O\cdot OH$ (Abstr., 1891, 1121), is the hydroxy-compound of which quinine and quinethyline are the corresponding methoxy- and ethoxy-compounds. The authors have now prepared quinopropyline, quinisopropyline, and quinamyline.

Quinopropyline, $C_{19}H_{21}N_2O\cdot OPr^{\alpha}$, is prepared by heating sodium cupreïne (3·2 grams of cupreïne, 0·35 gram of sodium) with propyl nitrate (1·6 grams) and propyl alcohol (50 c.c.) at 110° for 24 hours. The free base, which is precipitated as a hydrate on the addition of ammonia to the aqueous solution of the basic sulphate, melts at 100° in the hydrated condition, but at 164° after drying in a vacuum. It may be obtained in long needles by slow evaporation of its solution in dilute ammonia saturated with ether. The *basic sulphate*,

$$(C_{22}H_{25}N_2O_2)_2,H_2SO_4,1\tfrac{1}{2}H_2O,$$

crystallises from boiling solutions in silky, micaceous needles, from moderately dilute solutions in gelatinous agglomerates, and from cold solutions in large, single needles. It melts at 223—224°, and dissolves in 454 parts of water at 13°. Its specific rotatory power at 22° is $[\alpha]_D = +229{\cdot}5°$.

Quinisopropyline is prepared in the same way. The free base melts at 154°. The *basic sulphate*, $(C_{22}H_{28}N_2O_2)_2,H_2SO_4,H_2O$, crystallises from boiling solutions in colourless needles, but from cold solutions in small, kidney-shaped crystals aggregated into a horny mass. It dissolves in 367 parts of water at 10°, and has a rotatory power of $[\alpha]_D = +229{\cdot}2°$ at 22°.

Quinamyline is prepared by heating amyl chloride with a solution of sodium cupreïne in amyl alcohol at 105° for 15 hours. The crude product is treated with soda and shaken with ether, and the ethereal solution treated with very dilute sulphuric acid; alcohol is then added to the warm acid solution, and it is neutralised with ammonia. On concentration, the basic sulphate crystallises out and may be recrystallised from alcohol. The pure base is amorphous, and melts at 166·5—167°. Its solution in dilute sulphuric acid is fluorescent. The *normal sulphate* is amorphous. The *basic sulphate*,

$$(C_{21}H_{32}N_2O_2)_2,H_2SO_4,2H_2O,$$

crystallises in long needles on cooling its alcoholic solution. It is very soluble in alcohol, less so in water (1 in 4170 at 11·5°).

Jn. W.

Apocinchonine and Diapocinchonine. By E. Jungfleisch and E. Leger (*Compt. rend.*, **114**, 1192—1195).—The apocinchonine formed by the action of dilute sulphuric acid on cinchonine (*Compt. rend.*, **113**, 653) exists in that part of the product which is insoluble in ether and in dilute alcohol. This mixture is treated with strong

boiling alcohol, and after separation of the greater part of the cinchoniline and cinchonifine by fractional crystallisation, the mother liquor is mixed with a small quantity of alcohol and then diluted with its own volume of water. The apocinchonine separates and may be recrystallised from strong alcohol; the oxycinchonines and other bases remain in solution. Further purification of the apocinchonine is effected by converting it into oxalate, which readily crystallises. It is identical with the apocinchonine obtained from cinchonine by the action of hydrochloric acid, but the action of sulphuric acid gives a much lower yield. No trace of the α- and β-oxycinchonines is found in the product of the action of hydrochloric acid, and their formation under the influence of sulphuric acid is most probably due to the intermediate formation of sulphonic derivatives, or some other specific action of the acid. It is clear that the oxycinchonines do not exist, as Hesse suggested, as impurities in the original cinchonine.

The diapocinchonine, stated by Hesse to exist in the alcoholic mother liquor from apocinchonine, is a mixture of cinchoniline and cinchonigine with another base not yet isolated. C. H. B.

Aconitine. By A. Ehrenberg and C. Purfürst (*J. pr. Chem.* [2], **45**, 604—613).—The aconitine was purified from a large commercial sample by recrystallisation from ether, only the middle fraction being used. The pure alkaloïd melts at 193—194° (compare Dunstan and Ince, Trans., 1891, 271), but the presence of a very small quantity of a decomposition product, which coats the crystals like a varnish and therefore escapes detection, lowers the melting point by 10° and more; for this reason the purification of aconitine by converting it into a salt and decomposing this by an alkali is inadmissible. The authors' formula for aconitine is $C_{32}H_{43}NO_{11}$; Wright and Luff give $C_{33}H_{43}NO_{12}$ (Trans., 1878, 152); Dunstan and Umney, $C_{33}H_{45}NO_{12}$ (*loc. cit.*; compare, however, Trans., 1892, 391). Determinations of methoxyl by Zeisel's method showed 9·92, 9·98, and 10·13 per cent. of methyl as methoxyl; the elimination of four methyl groups from the above formula would give 9·73 per cent.

When hydrolysed by alcoholic potash, or by water, at 140—150°, aconitine yields a new base, methyl alcohol, benzoic acid, and another acid (compare authors quoted). When it is heated with water in a reflux apparatus until it has all dissolved, picroaconitine and napelline are produced, and crystallise from the solution as benzoates; they may be approximately separated by treatment with dilute sulphuric acid, washing with ether to extract the liberated benzoic acid, adding sodium carbonate until there is a slight precipitate and again shaking with ether, which extracts the napelline; the picroaconitine is obtained by digesting the slightly alkaline solid residue with ether. The picroaconitine, $C_{25}H_{39}NO_{11}$, is probably formed from 1 mol. of aconitine by the absorption of 1 mol. of water and elimination of 1 mol. of benzoic acid, and the napelline, $C_{24}H_{37}NO_{10}$, from 1 mol. of picroaconitine, by the absorption of 1 mol. of water and elimination of 1 mol. of methyl alcohol. The mother liquors from the picroaconitine and napelline benzoates contain aconine, $C_{22}H_{35}NO_9$, and acetic acid; this points to the formation of 1 mol. of aconine from 1 mol. of

napelline by the absorption of 1 mol. of water and elimination of 1 mol. of acetic acid.

When aconine is distilled with barium hydroxide, paraffin hydrocarbons, methylamine, and an oily compound which boils at about 245° and has an odour of quinoline are obtained. This matter is being further investigated.

The so-called amorphous aconitine of commerce is a variable mixture of aconitine, picroaconitine, and napelline. A. G. B.

Scopolamine (Hyoscine). By E. Schmidt (*Arch. Pharm.*, **230**, 207—231; compare Abstr., 1891, 228).—Inasmuch as the name hyoscine has been misapplied to tropine, it has become somewhat ambiguous, and the author proposes to call the hyoscine from hyoscyamus, *scopolamine*, a name which is in accord with the recent isolation of this alkaloid from *Scopolia atropoïdes* (Abstr., 1890, 658).

Scopolamine, $C_{17}H_{21}NO_4 + H_2O$, crystallises well, and melts at 59° to a colourless liquid, which does not crystallise again. The aurochloride crystallises in needles, and melts at 212—214° (uncorr.), not 198° (Ladenburg, Abstr., 1881, 446), although a small quantity of an aurochloride, having the latter melting point, was obtained (compare Abstr., 1888, 856). The hydrobromide crystallises with 3 mols. H_2O, and the hydrochloride with 2 mols. H_2O, whilst the hydriodide and sulphate are anhydrous. The *acetyl* derivative was prepared, and its *aurochloride*, $C_{17}H_{20}AcNO_4,HAuCl_4$, was crystallised; the presence of a hydroxyl group is thus indicated. Nitrous acid has practically no action on scopolamine, which may, therefore, be regarded as a tertiary base. When boiled with baryta-water, scopolamine is split up into atropic acid and a base which the author designates scopoline, $C_8H_{13}NO_2$. This base boils at 241—243° (uncorr.) and melts at 110°; its aurochloride melts at 223—225°, and its platinochloride at 228—230°. The identity of scopoline is somewhat uncertain; its boiling point agrees with that of oxytropine (Abstr., 1884, 761); it also agrees in the temperature constants of itself and salts, but not in formula, with pseudotropine (Abstr., 1884, 761; 1891, 1265; this vol., 891). The isomerism of scopolamine with cocaïne is to be noted.

Scopolamine was also obtained from *Hyoscyamus niger*, *Atropa belladonna*, *Datura stramonium*, and *Duboisia myoporoïdes*.

A. G. B.

Subsidiary Alkaloïds of Belladonna. By E. Merck (*Arch. Pharm.*, **230**, 134—141).—According to our present knowledge, crude belladonine (the mother liquor from atropine crystallisation) contains atropamine, belladonine, and hyoscine, their decomposition products, tropine and pseudotropine, and the derivatives of these, atropic and isatropic acids. The more recent work on the subject will be found in Abstr., 1884, 761, 1055; 1890, 271; 1891, 228, 748.

Apoatropine was first prepared by Pesci (Abstr., 1882, 740). Its *hydrochloride*, $C_{17}H_{21}NO_2,HCl$, forms white, lustrous, anhydrous laminæ, which melt at 237—239°, and dissolve sparingly in cold water. The *hydrobromide* crystallises in long needles and lustrous,

white laminæ, and melts at 230°. The *hydriodide* forms small, white needles. The *aurochloride*, $C_{17}H_{21}NO_2,HAuCl_4$, crystallises in long, slender, yellow needles, dissolves sparingly in cold water, and melts at 110—111°. The *platinochloride*, $(C_{17}H_{21}NO_2)_2,H_2PtCl_6$, melts at 212—214° with decomposition. The *mercurochloride*,

$$C_{17}H_{21}NO_2,HHgCl_3,$$

stannochloride, *chromate*, and *picrate* (m. p. 166—168°) were also prepared. A comparison of these salts with those of Hesse's atropamine (Abstr., 1891, 228) leads to the conclusion that this base is identical with apoatropine; Hesse, however, did not crystallise atropamine.

Apoatropine was decomposed by alcoholic potassium hydroxide, and the basic products extracted with chloroform, leaving the acids to be extracted with ether after acidification. The chloroform solution having been dried over potassium carbonate and evaporated, left a base which boiled at 227—229° and solidified on cooling to a white, crystalline mass; the platinochloride melted at 201° with decomposition, and the aurochloride at 206°. These properties correspond with those of tropine. Hesse (*loc. cit.*) described the product of the decomposition of atropamine by alkalis as pseudotropine, but it is not identical with the pseudotropine obtained from hyoscine. The ethereal extract of the acidified decomposition product contained atropic acid. The author comes to the conclusion that apoatropine is identical with atropamine, and that Hesse's base (b. p. 242°) is pseudotropine. A. G. B.

Chlorocruorine. By A. B. Griffiths (*Compt. rend.*, **114**, 1277—1278).—Chlorocruorine exists in two states, namely, oxychlorocruorine, which shows absorption bands at λ 618—593 and at λ 576—554·5, and reduced or ordinary chlorocruorine, which shows a single badly defined band between C and D.

Chlorocruorine extracted by the method previously described (*Compt. rend.*, **114**, 840) has the composition

C.	H.	N.	Fe.	S.	O.	
54·23	6·82	16·16	0·45	0·78	21·56	= 100,

which corresponds with the formula $C_{560}H_{845}N_{143}FeS_3O_{167}$. When treated with acids and alkalis, it yields hæmatin, a proteïd, and fatty acids.

The ash of the blood of *Sabella* has the composition

Fe_2O_3.	CaO.	MgO.	K_2O.	Na_2O.	P_2O_5.	SO_3.	Cl.	
0·18	3·42	1·22	4·03	45·23	4·56	2·10	39·26	= 100·00

C. H. B.

Physiological Chemistry.

Respiration Apparatus. By J. Haldane (*J. Physiol.*, **13**, 419—430).—A simple and effective apparatus for measuring the respiratory exchange of small animals is described. It consists of five Woulff's bottles; between the second and third the animal chamber is placed; the series is connected by glass and india-rubber tubing. Air is drawn through the apparatus by a filter pump; a meter measuring the rate of ventilation. The first bottle is filled with soda-lime, the second with sulphuric acid and pumice stone. These deprive the atmospheric air of carbonic anhydride and moisture respectively. Bottles 3 and 5 are also filled with pumice stone and sulphuric acid; bottle 4, with soda-lime. Bottles 3, and 4 and 5 together, are weighed before and after the experiment. The increase of weight gives the moisture and carbonic anhydride produced by the animal. The absorption is very complete even with rapid ventilation (1 to 7 litres of air per minute). The oxygen absorbed is measured by the difference in the increase of weight of bottles 3, 4, and 5, and the loss of weight of the animal chamber with the animal within it.

For human beings Pettenkofer's apparatus is more convenient. It may, however, be much simplified by using soda-lime instead of baryta-water. W. D. H.

Formation of Uric Acid in Mammals. By F. Mares (*Monatsh.*, **13**, 101—110).—The author has previously (*Archives slaves de Biologie*, **3**, 207) advanced the view that uric acid is a product of change occurring within the living cell, but had not then determined which of the substances present in the cell gives rise to the acid. Horbaczewski (Abstr., 1891, 1340) has referred the formation of the acid to the nucleïn of the cell; and our present knowledge of the origin of the acid may be accordingly formulated:—"Uric acid is a product of metabolism occurring within the living cells of mammals, in the formation of which the nucleïn of the cell-nuclei is specially concerned." G. T. M.

Dissolved Nitrogen in Blood. By F. Jolyet and C. Sigalas (*Compt. rend.*, **114**, 686—688).—Parallel series of estimations of the volumes of nitrogen and hydrogen absorbed by blood of varying degrees of richness, with whole corpuscles, with broken up corpuscles, and with serum alone, show that the absorption of both these gases increases with the number of corpuscles, and is greatly diminished by breaking them up, and that the amount of nitrogen absorbed is always greater in corresponding experiments than the amount of hydrogen. It is, therefore, probable that the gases form a layer on the surface of the corpuscles, and this view is borne out by the well known fact that hydrogen adheres much less readily than any other gas to surfaces. Jn. W.

Absorption of Water from the Alimentary Canal. By J. S. Edkins (*J. Physiol.*, **13**, 445—459).—The animal (cat) is anæsthetised by morphine, and atropine injected subcutaneously, *plus* chloroform. A length of alimentary canal is tied off from the rest, cleaned, and normal saline solution introduced from a burette at constant pressure. The amount of secretion from the gastric and intestinal wall is small, and may be disregarded. A little mucus is generally found. The difference between the amount of liquid used, and the amount recovered at the end of the experiment, which always lasts one hour, gives the amount absorbed. This, divided by the length of the ligatured portion of the canal, gives the "coefficient of absorption," that is, the amount absorbed per centimetre per hour at the given pressure. A pressure of 10 cm. was usually employed.

The results obtained were the following:—

1. The absorption in the large intestine is considerable, the average coefficient of absorption being 2·07 c.c.

2. In the ileum, the coefficient of absorption is less constant, and averages 1·31 c.c.

3. In the jejunum it is 0·727 c.c.

4. In the stomach, whatever state of digestion it was in, the coefficient is practically nothing. W. D. H.

Ptomaïnes of Infectious Diseases. By A. B. Griffiths (*Compt. rend.*, **114**, 1382—1384).—*Glanders.*—The author has extracted from the urine of victims to glanders a ptomaïne which forms white crystals of the composition $C_{15}H_{10}N_2O_6$. The hydrochloride, platinochloride, and aurochloride are all crystalline. Its solutions give a greenish precipitate with phosphotungstic acid, a brownish-white precipitate with phosphomolybdic acid, a yellow precipitate with picric acid, and a precipitate with Nessler's solution. The base is poisonous, and when injected under the skin of a rabbit, produces abscesses at the point of injection, peculiar nodular lesions in the lungs, &c., and finally, death.

Pneumonia.—The ptomaïne from the urine of pneumonia patients forms white, microscopic needles, soluble in water, forming an alkaline solution. It forms a hydrochloride, platinochloride, and aurochloride, and its solutions give a white precipitate with phosphotungstic acid, a yellowish-white precipitate with phosphomolybdic acid, a yellow precipitate with picric acid, and a brownish precipitate with Nessler's solution. The base has the composition $C_{20}H_{26}N_2O_3$, and its specific rotatory power is $[\alpha]_D = +23·5°$.

Neither of these ptomaïnes is found in normal urine.

Chemistry of Vegetable Physiology and Agriculture.

Aërobic Nitrate-reducing Ferment in Straw. By E. Bréal (*Compt. rend.*, **114**, 681—684).—Straw always contains nitrates on its surface, as shown by the diphenylamine reaction, but after soaking in water for a few days, the nitrates disappear, and increasing quantities then added to the water also disappear. This action is due to a ferment, for if the straw is previously sterilised it does not take place, and the ferment is aërobic, for the action soon stops in the absence of air. The nitrates are reduced partly to free nitrogen, which can be collected and examined, and partly to nitrogen in organic combination. The reduction is not to be feared in ordinary humus soils, as the amount of water they contain is insufficient for the growth of the ferment, but in prairie and forest soils it probably forms an important factor in the cycle of change. Jn. W.

Respiration of Plants under Lessened Oxygen Tension, and when Injured. By Stich (*Bied. Centr.*, **21**, 350; from *Sitzungsber. Wien. Akad.*, 1890, 407).—The normal respiration and production of carbonic anhydride in hydrogen were determined, that is, by intramolecular respiration with complete exclusion of oxygen. The addition of 20·8, 8, 6, 4, 2, and 0 per cent. of oxygen showed the independence of the production of carbonic anhydride on the presence of atmospheric oxygen in rather wide limits, there being no striking diminution with 4 to 2 per cent. of oxygen. In the case of many objects, as, for instance, the fruits of *Jasminum fructicans* and *Sambucus nigra*, and the seedlings of *Ricinus communis*, *Vicia faba*, and *Lupinus albus*, the production of carbonic anhydride was not influenced by the amount of oxygen present, and was as great in an atmosphere of hydrogen as in air. The relation of the carbonic anhydride which was found to the oxygen taken up was not altered when 8 per cent. of oxygen was present, and when the experiment lasted from 3 to 24 hours. With 3—4 per cent. the quotient $CO_2 : O$ was altered in favour of CO_2.

Experiments were made with a large number of plants to ascertain the effect of injury (from scratches to complete cutting up) on respiration. An increased separation of carbonic anhydride was always noticed; but the various plants and parts of plants behaved differently with regard to the extent and duration of the increase.

Nutrition of Green Plant Cells with Formaldehyde. By T. Bokorny (*Landw. Jahrb.*, **21**, 445—465).—The artificial nutrition of green plant cells has been successfully accomplished by several investigators. Böhn (*Bot. Zeit.*, 1883) showed that some leaves, freed from starch, produced starch in a few days when placed on a solution of sugar. Similar results were obtained by Klebs (*Ber. deut. bot. Ges.*, **5**, 186), A. Meyer (*Bot. Zeit.*, 1885), and E. Laurent. Both Meyer and Laurent proved that mannitol and dulcitol will give rise to starch production, whilst with erythritol they obtained negative

results. They also showed (almost contemporaneously, *Bot. Zeit.*, 1886, 81) that glycerol is a starch-forming substance; this was also observed by the author, who further showed that ethylidene glycol and methyl alcohol have the same property (*Landw. Versuchs-Stat.*, 1889, 235). According to v. Baeyer's hypothesis, formaldehyde is an intermediate product in the production of carbohydrates from carbonic anhydride; the object of the experiments described in the present paper was to ascertain whether plant cells could produce starch when supplied with formaldehyde instead of carbonic anhydride. It has not yet been shown that formaldehyde even exists in plants. Owing to its poisonous nature and its great instability, it is unlikely that it occurs in sufficient amount to be detected (compare Reinke, *Ber. deut. bot. Ges.*, **14**, 2150).

In order to obtain plants free from starch, nutritive solutions free from potash were employed—potash being necessary, as Nobbe has shown, for starch production—whilst the already formed starch was eliminated by adding an excess of nitrate to the nutritive solution. In this manner it was possible to obtain Spirogyræ, free from starch, in a few days, even in full daylight. To prevent assimilation of carbonic anhydride during the experiment there are three methods: (1) keeping the plants in the dark, (2) employing an atmosphere free from carbonic anhydride, and (3) the omission of potassium from the nutritive solution. The first of these methods is, however, not always applicable in these experiments, as many of the organic substances are only assimilated in presence of light.

The organic compounds experimented with have to be employed in such amounts as are without injury to the plants. Solutions of methyl alcohol must not be stronger than 0·5 per cent.; sugar solutions may be employed, which contain as much as 10 to 20 per cent., whilst formaldehyde had to be diluted to 1 : 50,000 in order to keep the Spirogyræ alive for a few days; in fact, experiments with free formaldehyde had to be discontinued. Satisfactory results were, however, obtained with the double compound of formaldehyde with sodium hydrogen sulphite, which has already been employed by O. Loew in his experiments with fungi (*Bot. Centr.*, 1890). When the double compound is used, it is necessary to add some disodium hydrogen phosphate to the nutritive solution in order to convert the hydrogen sodium sulphite, when liberated, into the disodium salt. Care must also be taken to select a suitable plant: many plants are injured by the dialkali phosphate, whilst others decompose the formaldehyde too quickly, &c.

Satisfactory results were obtained with a small variety of Spirogyræ (*flavescens ?*), with *S. majuscula*, and with *S. nitida*. When exposed to light, there was considerable production of starch from formaldehyde in absence of carbonic anhydride, whilst experiments without formaldehyde showed no formation of starch. The results were confirmed by quantitative experiments, in which weighed amounts of Spirogyræ were shown to gain considerably in dry substance, and to form very large amounts of starch. Thus, an amount of *S. nitida* containing 0·21 gram of dry matter, grown in a solution containing sodium formaldehyde sulphite (0·1), disodium phosphate

(0·05), calcium nitrite (0·1), magnesium sulphite (0·025), and calcium chloride (0·05 per cent.), contained, after 10 days, 0·26 gram of dry matter, excluding portions which died during the experiment. A control experiment, without formaldehyde, showed that no starch was formed, and that there was no increase of dry matter. Other experiments gave similar results. Experiments were then made to ascertain the loss of formaldehyde which takes place: in a check experiment, without the plants, there was no loss, whilst with plants 145·8 milligrams (out of 250 milligrams) disappeared in 10 days.

Zygnema cruciatum.—A quantity of *Zygnema*, poor in starch, was put into a 250 c.c. stoppered flask containing the mineral nutritive solution with 0·2 per cent. of sodium formaldehyde sulphite. The algæ grew well, and formed considerable amounts of starch; they remained quite healthy, and no threads died in eight days. The experiment was repeated in a closed space, kept free from carbonic anhydride by means of potash, the nutritive solutions being kept in glass dishes. When formaldehyde was withheld, the algæ remained poor in starch, whilst in presence of formaldehyde there was a very great production of starch. Neither fungi nor infusoriæ were found, so that there can have been no evolution of carbonic anhydride.

The results of the experiments show that green plant cells have the power of decomposing sodium formaldehyde sulphite and immediately condensing the formaldehyde liberated. Light plays an important part in the synthesis, and in a feeble light the starch formation is very slow, whilst in absence of light no carbohydrate is produced. Under the influence of light and formaldehyde, the plants gain considerably in dry matter in absence of carbonic anhydride.

Fat-decomposing Ferments in Plants. By W. Sigmund (*Bied. Centr.*, **21**, 350; from *Sitzungsber. Wien. Akad.*, 1890, 407, and 1891, 328).—The experiments were made with oily seeds, chiefly rape. The ferments soluble in water and glycerol, but insoluble in alcohol, were dried at 30° and mixed to an emulsion with weighed amounts of fatty oils. In 24 hours, titration with decinormal alkali showed a distinct increase of free acid. The action of the ferment is of similar (less) intensity to that of the pancreas ferment. Subsequent experiments showed that the co-operation of an organised ferment in the decomposition of the oil is not possible, and the ferment of the seeds showed the characteristic property of all enzymes, being when dry soluble at 100°, but when damp it loses its activity at 80°, so that heated dry seeds gave active, boiled seeds inactive, extracts. Experiments with germinating seeds gave similar results, except that the increase of acid was considerably greater, and that the ferment of the germinated seeds seemed to be more sensitive to heat in the dry state. The ferment has also the power of decomposing alkyl salts, as, for instance, spermaceti, which do not, like glycerides, belong to fats in the narrower sense.

N. H. M.

Influence of Phosphoric Acid on the Formation of Chlorophyll. By O. Löw (*Forsch. a. d. Gebiete d. Agrik.-physik.* **15**, 100; from *Bot. Zentralbl.*, **48**, 371).—Threads of *Spirogyra majuscula* kept

in a solution containing calcium nitrate (0·02) and ammonium sulphate (0·002 per cent.) lived for weeks in diffused daylight. The cells grew, but the increase of the mass seemed very slight. The chlorophyll band was pale-yellow, but was still active, although much less so than under normal conditions. Iron sulphate (0·002 per cent.) was added without any result, but the further addition of disodium phosphate (0·08 per cent.) caused greenness. No unhealthy appearance was observed, owing to the absence of potassium and magnesium. The results support the view that phosphoric acid is necessary as well as iron for the production of a normal chlorophyll. N. H. M.

Origin of the Colouring Matters of the Vine. By A. Gautier (*Compt. rend.*, **114**, 623—629).—See this vol., p. 1242.

The Constituents of Menyanthes trifoliata and of Erythræa centaurium. By K. Lendrich (*Arch. Pharm.*, **230**, 38—60).—To isolate menyanthin from the ethereal extract of *Menyanthes trifoliata*, the ether is evaporated, the residue extracted with water, and the aqueous solution shaken with moist aluminium hydroxide to eliminate tannin; it is then evaporated in a vacuum, the residue treated with absolute alcohol, the solution filtered, distilled to a small volume, mixed with ether, and again filtered; the ether is evaporated, the alcoholic residue boiled with animal charcoal in a reflux apparatus, and finally evaporated in a current of carbonic anhydride. Directions are also given for the isolation of menyanthin from an alcoholic extract of the plant.

Menyanthin, $C_{33}H_{50}O_{14}$, as first obtained is a yellow substance having the consistency of turpentine, a neutral reaction, and bitter taste; when dried in an atmosphere of hydrogen in a current of steam, it becomes solid, and has a glassy fracture. Its aqueous solution gives the following precipitates:—yellow with potassium bismuthoiodide, white with potassium mercuric iodide, yellow with sodium phosphomolybdate, white with tannin, yellow with iodine solution; gold chloride and Fehling's solution are reduced by it. Hot lime-water and baryta-water decompose the aqueous solution. Picric and oxalic acids are among the products of the decomposition of menyanthin by nitric acid, and phenol-like substances are to be detected when it is melted with potassium hydroxide.

The menyanthol obtained by distilling menyanthin with dilute sulphuric acid is a yellow oil with a characteristic odour, but unlike that of benzaldehyde. It has an acid reaction, and in some respects behaves both as an aldehyde and as a phenol; on this account alone, Kromayer's formula, C_8H_8O, for this substance is probably incorrect, and the author's analyses show that $C_7H_{11}O_2$ is the most likely empirical formula. The sugar which is formed when it is decomposed by dilute sulphuric acid is lævorotatory.

Erythrocentaurin, $C_9H_{14}O_6$, is isolated from *Erythræa centaurium* by the same method as that adopted for menyanthin. It is nearly colourless, turpentine-like, bitter, and neutral; it will not crystallise, but dries up, resembling menyanthin in this respect, as also in its solubility and reactions. When distilled with dilute sulphuric acid, it

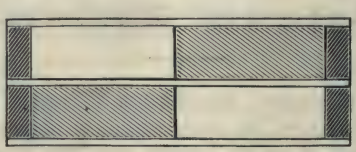
yields resinous matters, a substance which is both aldehydic and phenolic in properties, and a sugar.

For the investigation of the fatty matters in *Menyanthes trifoliata*, the ether extract from which the menyanthin has been dissolved by water is saponified and extracted by ether, the ether evaporated, and the residue treated with acetone; in this way, ceryl alcohol and a cholesterol can be isolated, whilst formic, acetic, and butyric acids are found in the mass of alkaline salts produced by the saponification. Palmitic acid was also detected, but neither oleïc acid nor glycerol. A red colouring matter is left in the acetone solution after the cholesterol has been separated; it may be purified by evaporating the acetone and extracting with methyl alcohol, in which the red matter is insoluble. This red substance appears to be a fatty ethereal salt of cholesterol, identical with the so-called carrotin. A. G. B.

The Fruit of Capsicum annum. By T. Pabst (*Arch. Pharm.*, **230**, 108—134).—The alkaloïd-like substance obtainable in traces from the fruit of *Capsicum annum* is not a normal constituent thereof, but a decomposition product which is formed during the storage of the fruit, or else by the action of chemical agents. The pungent substance, the so-called capsaicin, behaves towards metallic salts as an amorphous acid, and is intimately mixed with a red colouring matter; the latter resists all attempts to separate it from the acid, and it is an open question whether the colouring matter is combined with the acid or not. The pungent substance is also closely associated with free fatty acids, namely, oleïc, palmitic, and stearic acids. The colouring matter was not actually identified with carrotin, although it appears to be a fatty ethereal salt of cholesterol (compare Thresh, Abstr., 1878, 233). A. G. B.

Analytical Chemistry.

Estimation of Glycerol in Sweet Wines. By M. T. Lecco (*Ber.*, **25**, 2074—2075).—The author adds a large excess of calcium hydroxide to the wine, namely, 1 gram per 10 c.c. The estimation of the glycerol is then carried out as usual by the method previously described (*Chem. Zeit.*, **14**, 504). E. C. R.



Behaviour of Aldehydes and Ketones with Aromatic Nitro-compounds. By B. v. Bittó (*Annalen*, **269**, 377—382; compare this vol., p. 924).—Many aldehydes and ketones give with certain aromatic nitro-compounds in presence of potash, and of alcohol also if necessary for solution, a more or less intense colour reaction; in the case of metadinitrotoluene, for example, a blue, in the case of α-dinitronaphthalene, an intense red, coloration is produced.

The author gives in a table the results of an examination of the behaviour of a large number of aldehydes, ketones, and ketonic acids with metadinitrobenzene, in presence of alkali; the effect produced by the subsequent addition of an organic acid is also stated.

From his observations he draws the conclusion that a colour reaction is given by all fatty aldehydes and fatty ketones which contain a non-substituted $CH_n \cdot CHO$ or $CH_n \cdot CO$ group respectively, by all mixed ketones, and by those aromatic aldehydes which contain a fatty radicle. F. S. K.

Volumetric Estimation of Peptones in Urine. By Roux (*J. Pharm.* [5], **25**, 544—545).—Fehling's solution run into a dilute solution of peptone passes through a colour change, light-blue, blue-violet, lilac, and rose-purple, to a greyish tint. The peptone solution is freed from albumin and reducing compounds, and decinormal Fehling's solution is employed, the titration finishing with the rose-purple tint. 1 c.c. of solution equals 0·004 gram of peptone. After a little practice, very concordant results can be obtained. J. T.

Colorimetric Estimation of Hæmoglobin. By F. Hoppe-Seyler (*Zeit. physiol. Chem.*, **16**, 505—513).—It is recommended that the standard of comparison in the colorimetric estimation of blood pigment should be a normal solution of carbonic oxide hæmoglobin instead of the tinted glass, carmine, &c., at present largely used. The carbonic oxide hæmoglobin for comparison should be prepared in large quantities, and in well-stoppered bottles it keeps for years. Its strength can be estimated in a sample. The liquid to be investigated should, by means of a stream of carbonic oxide, have its hæmoglobin converted into carbonic oxide hæmoglobin. It is then diluted until its colour is the same as that of the standard. The amount of dilution being known, the strength of the solution is easily ascertained. The instrument used is termed a capillary double pipette, and the principle of it can be understood by reference to the accompanying diagram representing a transverse section. It consists of three glass

plates with brass side walls (the darker shading in the figure); the two cavities are divided into four by two highly polished glass plates (shaded lighter in the figure). The remaining two compartments are filled respectively with the standard solution and the liquid to be investigated. The advantage claimed for the instrument is that, as optically a mere line separates the two liquids, the colour comparison is rendered extremely sharp. The instrument can also be used for spectroscopic and spectrophotometric observations.

W. D. H.

General and Physical Chemistry.

Influence of Boric Acid on the Electrical Conductivity of Dilute Alcoholic Solutions of Organic Acids. By G. Magnanini (*Gazzetta*, **22**, 541—558).—The author has arrived at the following conclusions respecting the effect produced by boric acid on the electrical conductivity of organic acids in solution:—(*a*) The addition of boric acid to the aqueous solution of organic acids containing no alcoholic hydroxyl never augments the electrical conductivity. (*b*) A greater or less increase in conductivity always attends the addition of boric acid to the aqueous solution of a hydroxy-acid which contains an alcoholic or phenolic hydroxyl in the α- or ortho-position relatively to the carboxyl group. (*c*) In the aqueous solution of a hydroxy-acid which does not contain the hydroxyl in the α-position to the carboxyl group, boric acid never causes an augmentation in the conductivity. These three laws give a method for solving the constitutions of a number of organic acids which are soluble in water; many such acids, however, are practically insoluble in water, and it becomes of importance to know whether a more or less dilute alcoholic solution of the acid obeys the above laws. This question the author has investigated, using aqueous solutions containing 18—73 per cent. of alcohol, and finds that the laws still hold.

The following acids were examined:—Trichlorolactic, β-hydroxybutyric, malic, levulinic, mucic, trichlorodiketopentamethylenehydroxycarboxylic, dibromoparahydroxybenzoic, ortho- and para-nitrosalicylic, ortho-, meta-, and para-cresotic, orthocoumaric, β-resorcylic, protocatechuic, guiacolcarboxylic, orsellinic, pyrogallolcarboxylic, gallic, α-hydroxynaphthoic, and quinic acids. In all these cases, the results obtained were consistent with the generally accepted constitutions of the acids.

The author has also studied the effect of boric acid on the conductivity of the sodium salts of certain organic acids, but with very little result up to the present. W. J. P.

Diffusion in Aqueous Solutions. By S. Arrhenius (*Zeit. physikal. Chem.*, **10**, 51—95).—By means of a modification of Scheffer's apparatus (*Zeit. physikal. Chem.*, **2**, 391), the author has investigated the rate of diffusion of a large number of substances, both electrolytes and non-electrolytes, in aqueous solution. The error in the diffusion constant he estimates in the most unfavourable circumstances to be 2 per cent., and, in general, the error of the single determinations to be about 1 per cent.

When a non-electrolyte (for example, alcohol) replaces a portion of the water of a salt solution, then the rate of diffusion into the mixed solvent is less than the rate when pure water alone is used. For not too great concentrations (of the non-electrolyte in water),

the following relation holds good between the coefficient of diffusion and the concentration :—

$$D_x = D_0 (1 - \frac{\alpha}{2} x)^2,$$

where D_0 is the diffusion coefficient in pure water, D_x that in an x-normal solution of the non-electrolyte, and α a constant depending on the nature of the non-electrolyte. This formula is similar to the formula which expresses the effect of an addition of a non-electrolyte on the electrical conductivity of an aqueous salt solution (compare this vol., p. 1038), the coefficient α being nearly the same in the two cases. α is not greatly dependent on the nature of the diffusing substance.

When an electrolyte is added to the solvent instead of a non-electrolyte, there is usually a diminution of the diffusion constant, the influence on the rate of diffusion being very similar to the influence on the fluidity, as the following table shows :—

		Diffusion.	Fluidity.
1-*n*	KCl	0·997	1·013
„	NH_4Cl	0·986	1·024
„	$NaNO_3$	0·97	0·937
„	NaCl	0 915	0·932
„	$\frac{1}{2}(Na_2SO_4)$	0·845	0·814
„	$CH_3 \cdot COONa$	0·75	0·719

The author discusses at length the mechanism of diffusion phenomena, and shows that whilst the osmotic pressure theory, as applied by Nernst, explains the observed facts, the assumption of an attractive force between the molecules of the solvent and the molecules of the dissolved substance fails to do so. He is of opinion, however, that the relation between osmotic pressure, π, and concentration, K, may best be expressed by the formula $\pi = AK + BK^2$, where B is a constant which expresses the difference of the attractions of the dissolved for the solvent molecules and of the dissolved molecules amongst themselves. In dilute solutions, the second term vanishes, as compared with the first, and the osmotic pressure is then proportional to the concentration.

When hydrochloric acid diffuses, not into pure water, but into a solution of one of its salts, say of sodium chloride, the diffusion constant, instead of diminishing, increases. The author shows that this apparently anomalous case is capable of easy explanation on the assumption of the theory of electrolytic dissociation, and, from this hypothesis, calculates the constants for a number of similar cases. A selection of his results is contained in the table on page 1267.

The constant of diffusion has long been known not to be quite independent of the concentration of the diffusing solution, sometimes increasing, sometimes diminishing, with this. The author shows, on the osmotic pressure theory, that the relation between them may be expressed (for a non-electrolyte) as follows :—

$$K_c = K_\infty (1 + DC)(1 - \alpha C/2)^2,$$

Diffusing substance.	Solvent.	Diffusion constant (at 12°). Found.	Calculated.
HCl (1·04-norm.) .	Water	2·09	—
,, ..	0·67-*n* NaCl ..	3·51	3·58
,, ..	0·1-*n* ,, ..	2·50	2·43
,, ..	0·75-*n* KCl ...	4·22	4·08
,, ..	0·25-*n* ,, ...	3·08	3·10
NaOH (0·54-norm.)	Water	1·15	—
,,	0·25-*n* NaCl ..	1·90	2·02
,,	0·067-*n* ,, ..	1·51	1·52
,,	1-*n* ,, ..	1·98	2·17
,,	3-*n* ,, ..	2·30	2·40

where K_c is the diffusion constant for the concentration C, K_∞ the constant for infinite dilution, and α and D two coefficients which may be determined. According as D is greater or less than α, the diffusion constant will increase or decrease with the concentration. Examples are given, and the case of electrolytes is also discussed, the author replying to objections raised by Wiedeburg (Abstr., 1891, 383) against the new theory, and criticising the experimental method adopted by him.

By thermodynamical reasoning, the author shows that the osmotic pressure is proportional to the lowering of the freezing point for depressions less than 2°. J. W.

Determination of the Specific Gravity of Gases. By H. Moissan and H. Gautier (*Compt. rend.*, **115**, 82—86).—A flask fitted with a stop-cock is filled with perfectly dry air and weighed. The greater part of the air is then pumped out, and a known volume (about 100 c.c.) of the gas under examination is transferred to the flask by means of a graduated gas pipette. Dry air is allowed to enter the flask until the pressure is only slightly below that of the atmosphere, and the flask is again weighed. The difference between the first and second weighings, after correction for pressure, is the difference between the weight of the measured volume of gas and an equal volume of air. The error does not exceed 1 per cent., even in the case of gases whose sp. gr. is almost the same as that of air.

C. H. B.

Passage of Substances in Solution through Mineral Filters and Capillary Tubes. By C. Chabrié (*Compt. rend.*, **115**, 57—60).—In a previous note (*Compt. rend.*, **113**, 600), the author has shown that when albuminous urine is filtered through porcelain, the urea passes more quickly than the albumin, and when defibrinated blood is treated in the same way, the albumin and hæmoglobin concentrate in the later portions of the filtrate, and the hæmoglobin filters more slowly than the albumin. When a solution of urea and uric acid is filtered, the two substances pass through with equal rapidity. The results show that when two substances of large but unequal molecular volumes are filtered, that with the smaller volume filters more

quickly than the other, whilst with two substances of small though unequal molecular volumes the difference is too small to be recognised.

When a solution of albumin is passed through a capillary tube, of 0·05 mm. mean diameter, the albumin passes through less rapidly than the water. There is consequently a concentration of albumin in the reservoir, and if the solution becomes too strong, its passage through the tube ceases. No chemical change takes place, for if the whole of the liquid is forced through the tube, its composition at the end of the experiment is the same as at the beginning.

A solution of urea and Congo-red (mol. wt. 826) showed no difference in the rates of transpiration of its constituents. It follows that the phenomenon is only shown by substances with molecular weights which, like that of albumin, approach 10,000 to 15,000.

C. H. B.

Dissociation Constants of Stereoisomeric Nitrogen Compounds. By A. Hantzsch and A. Miolati (*Zeit. physikal. Chem.*, **10**, 1—33).—α-Oximido-acids which (according to the hypothesis advanced by Hantzsch and Werner to explain the stereoisomerism of the nitrogen compounds) have the carboxyl and the hydroxyl groups in the neighbouring positions are considerably feebler than the corresponding acids with these groups in the opposed positions. Thus phenylsynketoximecarboxylic acid, $\begin{matrix}C_6H_5\cdot C\cdot COOH\\ \|\\ N\cdot OH\end{matrix}$, has a dissociation constant of 0·18, whilst phenylantiketoximecarboxylic acid, $\begin{matrix}C_6H_5\cdot C\cdot COOH\\ \|\\ HO\cdot N\end{matrix}$, has a constant of 1·55. Both acids are feebler than the ketonic acid (phenylglyoxylic acid, $K = 6·31$) from which they are derived. The anti-acid in aqueous solution passes gradually into the syn-acid. The progress of this reaction may be followed by determining the electrical conductivity at different times. In the case of β-oximido-acids, the anti-compound is weaker than the syn-compound.

The authors obtained the following numbers for dioximido-acids :—

Glyoximecarboxylic Acids.

$\begin{matrix}H\cdot C\text{——}C\cdot COOH\\ \|\quad\quad\|\\ HO\cdot N\quad HO\cdot N\end{matrix}$, $K = 0·417$; $\begin{matrix}H\cdot C\text{—}C\cdot COOH\\ \|\quad\|\\ HO\cdot N\quad N\cdot OH\end{matrix}$, $K = 0·285$.

Methylglyoximecarboxylic Acids.

$\begin{matrix}CH_3\cdot C\text{————}C\cdot COOH\\ \|\quad\quad\quad\|\\ N\cdot OH\ HO\cdot N\end{matrix}$, $K = 1·39$; $\begin{matrix}CH_3\cdot C\text{——}C\cdot COOH\\ \|\quad\|\\ N\cdot OH\ N\cdot OH\end{matrix}$, $K<1·39$.

Glyoximedicarboxylic Acids.

$\begin{matrix}COOH\cdot C\text{————}C\cdot COOH\\ \|\quad\quad\quad\|\\ N\cdot OH\ HO\cdot N\end{matrix}$ $K = 6·22$; $\begin{matrix}COOH\cdot C\text{——}C\cdot COOH\\ \|\quad\|\\ NO\cdot N\quad N\cdot OH\end{matrix}$, $K = 1·05$.

The acids with the smaller constants are the more stable, the

stronger acids being gradually converted into them, by autocatalysis, in aqueous solution. J. W.

Affinity Coefficients of Acids. By E. Lellmann (*Annalen*, **270**, 204—208; compare Abstr., 1891, 638 and 1149).—The author and Schliemann have measured the relative affinity of a number of acids by a spectro-photometric method, analogous to that previously employed by the author and Gross in the case of bases, and described in the following abstract. The results obtained, within very wide limits of concentration, are in complete agreement with Guldberg and Waage's law, but they cannot be compared or brought into line with Ostwald's values of the electrical conductivity of the acids; the author considers that the affinity constants determined by the spectro-photometric method express in a more simple and direct way than can be done by the dissociation constants, the connection which exists between chemical change and the nature of the interacting substances. F. S. K.

Affinity Coefficients of Acids. By E. Lellmann and J. Schliemann (*Annalen*, **270**, 208—235).—The method employed for the measurement of the relative affinity of acids is, briefly, the following:—A measured quantity (25 c.c.) of a solution of 2 milligram equivalents (0·448 gram) of pure metahydroxyanthraquinone in 1 litre of 96 per cent. alcohol is mixed with a definite quantity of a solution of known strength of the pure barium salt of the acid, the mixture diluted to 50 c.c., and examined with a spectro-photometer; its absorption is then compared with that of a solution of the same quantity of metahydroxyanthraquinone in excess of barium hydroxide. The alcohol and the water used in the preparation of the solutions are carefully purified from basic substances by distillation over potassium hydrogen sulphate, and the glass vessels in which the solutions are kept are carefully freed from alkali by prolonged digestion with very dilute sulphuric acid; in cases where the barium salt is too sparingly soluble, a solution of the potassium salt is employed.

The results of the measurements are given in the following table: κ denotes the number of equivalents of the salt of the acid, compared with the number of equivalents of hydroxyanthraquinone salt, which are present in a solution containing equivalent quantities of hydroxyanthraquinone acid and base.

	κ.		κ.
Formic acid	61·97	Paramidobenzoic acid	7·60
Acetic acid	14·33	Nicotinic acid	43·02
Cinnamic acid	17·74	Picolinic acid	18·75
Benzoic acid	20·71	Isonicotinic acid	47·36
Orthotoluic acid	21·91	Lactic acid	39·94
Metatoluic acid	16·47	α-Hydroxyisobutyric acid	37·94
Paratoluic acid	15·22	Propionic acid	11·68
Orthamidobenzoic acid	11·40	Cinchonic acid	61·61
Metamidobenzoic acid	15·56		

The authors give a table comparing the affinity constants measured in this way with those determined by Ostwald; they are of opinion that the lack of agreement between the two series of observations is due to the fact that different solvents were used in the two cases. Special experiments proved clearly that the nature of the solvent has, under certain circumstances, a very considerable influence on the affinity constants as determined either by the spectrophotometric or by the electrical method, but even when the same solvent is employed in both cases the results do not agree.

F. S. K.

Autocatalysis. By U. Collan (*Zeit. physikal. Chem.*, **10**, 130—140).—The author has investigated the reaction velocity of the transformation of hydroxymethylbenzoic acid into phthalide in aqueous solution, and finds that it obeys the formula $-\frac{dC}{dt} = \delta C(1 - \delta)C \cdot K$, where C is the concentration, δ the proportion of the acid dissociated, and K the constant of the reaction. This is in agreement with the results obtained by Henry (p. 1303). Equations are also developed for the catalysis proceeding in presence of an acid (glycollic acid) which has the same dissociation constant as the acid catalysed. The agreement between calculation and experiment is good.

J. W.

Correlation of Oxygen and Hydrogen Compounds of the Elements. By F. Flavitzky (*J. pr. Chem.* [2], **46**, 57—85).—The compounds of non-metallic elements with hydrogen and oxygen can be referred to types consisting of hydroxyl, or of hydroxyl and hydrogen, combined with the element. The number of hydroxyl groups and hydrogen atoms is determined by the group of the periodic system into which the element falls. Thus, the stable hydroxy-compounds of an element in the fifth group can be regarded as anhydrides, derived by the loss of water from an original type consisting of 5 hydroxyl groups, or m hydroxyl groups and $5-m$ hydrogen atoms, united with the element. The tendency of the hydroxy-halogen acids to form stable hydrates, the inactivity of anhydrous hydrogen chloride, and the existence of many hydrated and double salts are explicable according to the author's theory, and many examples are adduced in the paper.

Inorganic Chemistry.

Mutual Displacement of Haloïds. By Miss P. Lazareff (*J. Russ. Chem. Soc.*, **22**, 383—385).—The chlorides of sodium and potassium were sealed up in tubes, along with bromine and with iodine, dissolved in carbon tetrachloride, and were allowed to remain for eight months at the ordinary temperature in the absence of light.

Similar experiments were made with iodine and the bromides of sodium and potassium. No change took place. J. W.

Composition of Water, and Gay Lussac's Law of Volumes. By A. Leduc (*Compt. rend.*, **115**, 41—44).—The author has redetermined the gravimetric composition of water, using a modification of Dumas' method. The copper oxide was prepared by oxidising very thin sheets of electrolytic copper, and was afterwards reduced at the lowest possible temperature in pure and dry hydrogen, the tube being wrapped in platinum foil. The last two tubes of the condensing apparatus were surrounded by ice and salt. The results show that the atomic weight of oxygen is 15·88, whilst its sp. gr. with reference to hydrogen, according to the author's determination (Abstr., 1891, 1416), is 15·90. It follows that the atomic weights, as determined by Stas, should be multiplied by 0·995. The results afford remarkable confirmation of Gay Lussac's law of volumes, but show that this law, like that of Boyle, is only true within certain limits. C. H. B.

Efflorescence of Metallic Sulphates. By H. Baubigny and E. Péchard (*Compt. rend.*, **115**, 171—174).—The rate at which various sulphates lose their water of crystallisation when exposed to dry air is considerably increased when they are crystallised from slightly acid solutions. 8·0 grams of copper sulphate, for instance, crystallised by vacuum evaporation of a solution containing 0·15 per cent. of free sulphuric acid, lost 4·875 grams in 65 hours, whilst 7·3 grams, crystallised in the same way from a solution neutral to methyl-orange, lost only 0·013 gram under identical treatment. The hexhydrate of cobalt nitrate also is much less stable when crystallised from acid solutions, although the heptahydrate does not show this difference. Zinc sulphate, again, loses its water more rapidly when crystallised from acid solutions, although the amount actually lost is the same in either case, a dihydrate being left. The double sulphates of cobalt and potassium, and of zinc and potassium, and the double ammonium alum of aluminium and chromium, behave in the same way, although the acidity of the mother liquor has to be much more strongly marked before the effect is apparent. Jn. W.

Action of Nitric Oxide on Metallic Oxides. By P. Sabatier and J. B. Senderens (*Compt. rend.*, **114**, 1476—1479).—The experiments described in a previous paper (this vol., p. 1151) have shown that nitric oxide acts as an oxidising agent on many metals and metallic oxides. Nitric oxide, however, tends to combine with oxygen to form nitric peroxide, and hence under some conditions acts as a reducing agent. At 150°, the reaction $NO + O = NO_2$ develops +16·7 Cal. The heats of formation of mercuric, cupric, ferric, and stannic oxides, by combination of the lower oxides with an atom of oxygen, are respectively +20, +38·2, +51·2, and +66 Cal., and are consequently higher than the heat of formation of nitric peroxide from nitric oxide. Direct experiment shows that these oxides are not reduced by nitric oxide below 500°. There is likewise no reduc-

tion in the analogous cases of molybdic, tungstic, titanic, and vanadic anhydrides, and uranic oxide.

On the other hand, the combination of silver, chromic oxide, and lead monoxide with one atom of oxygen to form respectively silver monoxide, chromic anhydride, and lead dioxide develops in the first case +7 Cal., in the second +2·1 Cal., and in the third +12·2 Cal. only. Chromic anhydride is reduced by nitric oxide at the ordinary temperature; silver oxide is reduced at 170°, and lead dioxide at 315°. Manganese dioxide is reduced to the sesquioxide by the action of nitric oxide at 400°.

When nitric oxide is passed into water containing lead dioxide, silver oxide, or manganese dioxide, appreciable quantities of nitrite are formed, even when air is entirely absent. The reaction is most distinct in the case of the lead compound, a solution containing 4 grams of lead nitrite per litre can be obtained; if the passage of the gas is prolonged, or if the liquid is concentrated, basic lead nitrite is formed. C. H. B.

Decomposition of Basic Nitrates by Water. By G. Rousseau and G. Tite (*Compt. rend.*, **115**, 174—175).—Copper subnitrate is completely decomposed by water at 150—160° into copper oxide and nitric acid, probably because the heat of dissolution of nitric acid in water, which is known to rise with the temperature, eventually becomes greater than its heat of combination with the oxide. The phenomenon appears to be fairly general, and occurs, for instance, with zinc, cadmium, and calcium subnitrates. Bismuth subnitrate may be completely decomposed into the oxide and acid by prolonged treatment (90 hours) with water at 200—205°. The water must be frequently changed, and marble must be added to take up the acid. Uranium subnitrate, prepared by heating the crystallised nitrate with marble in sealed tubes at 180—200°, and crystallising the product from alcohol, contains less acid the longer it is treated. Water completes the decomposition, the hydrate U_2O_3,H_2O being left. Jn. W.

Phosphorus Bromonitride. By A. Besson (*Compt. rend.*, **114**, 1479—1481).—When the compound of ammonia and phosphorus pentabromide (Abstr., 1891, 398) is heated at 200° under reduced pressure, it yields a small quantity of a white, crystalline sublimate insoluble in water. The yield can be increased by operating in the following manner:—The product of the action of dry ammonia on phosphorus pentabromide is heated in sealed tubes at 250—275° with about twice its weight of phosphorus pentabromide for 12 hours, and the semi-fluid magma obtained is heated under reduced pressure. Unaltered phosphorus pentabromide first sublimes, and at 200° the white sublimate forms and can be purified by resublimation in a vacuum. The product thus obtained is *phosphorus bromonitride*, PBr_2N. It forms colourless, highly refractive, seemingly rhombohedral crystals, which melt at 188—190° and begin to sublime at 150° in a vacuum; they are soluble in ether, less soluble in carbon bisulphide or chloroform, and insoluble in water.

A larger yield of the chloronitride (this vol., p. 1152) is obtained if

a layer of phosphorus pentachloride is first formed on the walls of a large flask by the action of chlorine on the trichloride, and then treated with ammonia until superficially saturated. The solid crust is then broken up and heated under reduced pressure. It will be seen that under these conditions the ammoniacal phosphorus pentachloride is heated in presence of the unaltered pentachloride which formed the lower part of the crust on the walls of the flask.

C. H. B.

Silicon Tetrachloride. By G. Rauter (*Annalen*, **270**, 235—266).—When silicon tetrachloride is heated at 270—370° severally with beryllium, magnesium, zinc, and aluminium, it is partially decomposed, but no reaction occurs with sulphur or with iron; it is not acted on by carbon bisulphide or chloride of sulphur, or by the sulphides of sodium, potassium, mercury, arsenic, and antimony even at 350—400°, but it is decomposed to a very slight extent by potassium bromide and by potassium iodide with liberation of silicon and a halogen.

Silicon tetrachloride is decomposed by nearly all metallic oxides, either at the ordinary temperature or on heating, with formation of silica; also by alkali carbonates and by nitrite, nitrate, chromate, dichromate, sulphate, permanganate, and chlorate of potassium; it is not decomposed by the oxides of carbon.

When silicon tetrachloride is heated with butyric acid at 150—160°, silica, hydrogen chloride, and butyric chloride are formed; with acetic anhydride, it yields acetic chloride and silica, but with phthalic anhydride there seems to be no action. Lead formate and silicon tetrachloride react at 240—250°, yielding silica, lead chloride, carbon monoxide, and hydrogen chloride; potassium acetate and silicon tetrachloride give potassium chloride, silica, and acetic chloride. Ethyl butyrate and ether are not acted on by silicon tetrachloride at 150—160°.

F. S. K.

Examination of Different Forms of Carbon. By J. Wiesner (*Monatsh.*, **13**, 371—410).—The author has subjected the various forms of carbon to the action of a mixture of sulphuric acid and potassium dichromate, and observed under the microscope the changes which take place. The chief results are as follows:—

The purest form of charcoal, obtained by heating the soot from a gas flame successively in currents of chlorine, nitrogen, and hydrogen, is slowly attacked by chromic mixture in the cold, and more quickly on warming; the action is much more rapid than with any of the other varieties of carbon, probably owing to its very finely divided state. Lignite is seen under the microscope to consist of brown, transparent particles, which rapidly become colourless on treatment with chromic mixture, leaving a skeleton tissue of cellulose, the histological character of which is frequently no longer recognisable. If the action of the chromic mixture is continued, this is also destroyed.

All the other varieties examined, namely, anthracite, bituminous coal, wood charcoal, soot, and graphite, contain a small quantity of an easily oxidisable substance, which is quickly dissolved by the chromic mixture, leaving a residue which is only very slowly attacked by it, no visible change taking place for weeks at the ordinary tempera-

ture. Anthracite consists almost entirely of amorphous carbon with a small quantity of a deep brown substance, which is slowly attacked by the oxidising agent, but leaves no residue of cellulose. Bituminous coal behaves in this, as in other respects, like a mixture of lignite and anthracite, and therefore leaves small quantities of cellulose on treatment with the acid mixture. Wood charcoal prepared at a low temperature, such as is used in the manufacture of gunpowder, is completely dissolved by chromic mixture, leaving at a certain stage a skeleton of cellulose which dissolves after a time. The wood charcoal obtained at a high temperature is, on the other hand, only attacked to a slight extent. Freshly prepared soot consists partly of fine black particles, which are hardly attacked by the acid, and partly of oily drops; the soot deposited from the atmosphere contains similar particles of carbon, which are sometimes united to form dendritic or irregular aggregates. Finely divided graphite also contains very small quantities of an oxidisable substance, and, although less acted on by chromic mixture than the amorphous variety, is not totally indifferent to the reagent.

The black lung pigment, which collects in the human lungs during life, behaves under the microscope in exactly the same manner as the black soot particles, and remains unaltered after several weeks' treatment with chromic acid. The melanin pigments, on the other hand, are rapidly attacked by the acid, the action being frequently complete in a few minutes. The pigment must therefore be derived from the soot contained in the air, and is not, as has been frequently supposed, formed within the organism itself.

The author also corrects the statement that has been made as to the transparency of amorphous carbon in a finely divided condition, his own observations having led him to the contrary conclusion.

H. G. C.

Supersaturated Aqueous Solutions of Carbonic Anhydride. By L. Pratesi (*Gazzetta*, **22**, 493—498).—The author has observed that certain mineral springs contain a larger quantity of carbonic anhydride in solution than is indicated by Bunsen's observations. For example, a mineral water from Contursi, in Salermo, issues at a temperature of 40° and contains 1·7605 grams of free carbonic anhydride per litre. Ordinary seltzer water, when drawn from the siphon and allowed to remain in the air for half an hour, still contains 1·901 litres of carbonic anhydride at 8° and 764·75 mm. pressure per litre: under these conditions of temperature and pressure, Bunsen found that distilled water dissolves 1·289 litres only of the gas. Distilled water, when saturated with carbonic anhydride in a siphon under pressure and then drawn off and allowed to remain for half an hour, was found to contain 1·858 litres of the gas at 9·5° and 770·65 mm. pressure per litre. The quantity of carbonic anhydride dissolved by 1 litre of distilled water at this temperature and pressure is 1·225 litres according to Bunsen.

It would hence seem that water first saturated with carbonic anhydride under pressure and then left for a short time under the ordinary pressure, contains a much larger quantity of carbonic anhydr-

ide than water simply saturated with the gas under ordinary pressure. W. J. P.

Lithium Bromate. By A. Potilitzin (*J. Russ. Chem. Soc.*, **22**, 392—393).—Lithium bromate was prepared in solution by the action of lithium sulphate on barium bromate. The solution was evaporated on the water-bath to incipient crystallisation, and afterwards placed over sulphuric acid in a bell jar. Anhydrous lithium bromate, $LiBrO_3$, crystallised out in apparently rhombic crystals, with well developed pyramidal faces. The hydrated salt, $LiBrO_3,H_2O$, was also obtained. J. W.

Double Chlorides of Lithium and Metals of the Magnesium Series. By A. Chassevant (*Compt. rend.*, **115**, 113—115).—Manganese, iron, nickel, and cobalt form isomorphous, double chlorides with lithium of the type $MCl_2,LiCl,3H_2O$. They have the colour of the anhydrous chloride of the dyad metal that they contain, and are easily dissociated by water, but are stable in presence of excess of lithium chloride. They form acicular crystals which, in a dry atmosphere, effloresce and lose hydrogen chloride. C. H. B.

Rate of Decomposition of Calcium Chlorate by Heat. By A. Potilitzin (*J. Russ. Chem. Soc.*, **22**, 333—346; compare Abstr., 1890, 696).—Calcium chlorate was prepared in the pure state by crystallisation of the commercial salt from aqueous solution. It crystallises with 2 mols. H_2O, and deliquesces in the air. The author could not confirm Wächter's observation that the salt melts on rapid heating to a temperature above 100°, but found that it is decomposed into the anhydrous salt and water. The anhydrous salt may be obtained crystalline by allowing the partially fused mass to evaporate slowly over sulphuric acid. The hydrated salt loses all its water of crystallisation on prolonged heating at 100°.

Anhydrous calcium chlorate begins to give off oxygen before it fuses, but between the limits 300—350° it melts after having lost from 3 to 5 per cent. of its weight of oxygen. The rate of decomposition at 330° increases until about 60 per cent. of the total oxygen has been evolved, after which it continually diminishes, the fused mass becoming solid when the salt has lost about 80 per cent. of its oxygen. The calcium chloride remaining is in the form of thin, transparent, needle-shaped crystals. On being dissolved in water, the residue exhibits an alkaline reaction. In the accompanying table (p. 1276), the connection between the composition of the mass and the quantity of oxygen given off is indicated. The temperature of experiment was 329—330°, and the numbers express percentages.

For various stages of the reaction at different temperatures, the author gives equations similar to those expressing the decomposition of strontium chlorate (Abstr., 1890, 697). The quantity of perchlorate formed is relatively much less than in the case of the strontium and barium salts.

Oxygen evolved (loss of weight).	Total chlorate decomposed.	Chlorate converted into chloride.	Chlorate converted into perchlorate.
6·00	13·48	13·20	0·28
9·40	21·59	20·40	1·17
10·78	25·13	23·77	1·36
15·00	34·47	32·51	1·87
20·97	47·78	45·51	2·26
27·43	61·56	59·21	2·34
31·77	70·32	68·01	2·31
39·74	86·12	84·23	1·92

J. W.

Basic Calcium Nitrate. By A. Werner (*Compt. rend.*, **115**, 169—171).—Milk of lime is added to a cold, saturated solution of calcium nitrate until it ceases to be dissolved; the solution is then shaken, and after some minutes sets to a semi-solid mass of long needles. This is protected from carbonic anhydride, and left for two or three days, after which it is collected on an asbestos filter by means of a filter pump. The *basic nitrate* thus obtained is dried on glazed porcelain in an atmosphere free from carbonic anhydride. It has the composition $Ca(NO_3)_2,Ca(OH)_2,2\frac{1}{2}—3H_2O$, and loses its water of crystallisation at 160°. It is decomposed by water into calcium nitrate and hydroxide. The heat of formation of the anhydrous salt is +2·0 Cal., and a further amount of 8·4 Cal. is developed in the formation of the hydrated salt. Jn. W.

Influence of the Composition of the Glass of Slides and Cover-glasses on the Durability of Microscopic Objects. By R. Weber (*Ber.*, **25**, 2374—2377).—It has been observed that objects well sealed between the cover-glass and slide sometimes lose the sharpness of their outline after a short time, and the glass becomes dim. The author finds that this is due to the composition of the glass. Those glasses which contain an excessive amount of alkali soon lose their lustre and become dim when exposed to moisture. The analysis of a colourless object glass, which did not retain its lustre, gave numbers corresponding with the ratio

$$SiO_2 : CaO : K_2O,Na_2O = 8·2 : 1 : 1·74.$$

Slightly green glasses, which contain more lime and less alkali, are more stable on exposure to air. Analyses of two sorts of cover-glasses, of which the first retained its lustre and the second did not, gave the ratios $SiO_2 : CaO : (K_2O,Na_2O) = 4·7 : 1 : 0·9$ and $6·6 : 1 : 1·1$ respectively. E. C. R.

Action of Potassium Sulphate on Strontium Carbonate. By E. Kouklin (*J. Russ. Chem. Soc.*, **22**, 322—326).—Strontium carbonate (1 mol.) was boiled up with a solution of potassium sulphate (40 mols.). After the boiling was over, the liquid was filtered and the precipitate washed with hot water. The mixed precipitate was treated with hydrochloric acid, and, to the solution obtained, alcohol was added to precipitate any strontium sulphate remaining

dissolved; this was added to what remained of the original precipitate; the whole was then washed with 80 per cent. alcohol and weighed. The strontium in the filtrate was precipitated by sulphuric acid, and weighed as sulphate.

The following numbers were found, corrections having been made for the solubility of the sulphate in water:—

Experiment.	Duration of boiling.	Strontium carbonate changed into sulphate.
I	5 hours	43·27 per cent.
II	17 „	56·74 „
III	48 „	65·88 „
IV	90 „	70·27 „

The number in Experiment IV is probably the limiting number, or very near it. There would thus be in the solution, which is in equilibrium with mixtures in any proportions of strontium sulphate and strontium carbonate, 55 mols. of potassium sulphate to 1 mol. of potassium carbonate.

0·9077 gram of strontium sulphate, boiled with a solution containing a large excess of potassium sulphate and carbonate in the proportion of 5 parts of the former to 1 of the latter, was all converted into carbonate, except 0·011 gram. But the quantity of sulphate which would go into solution in the liquid employed for boiling and for washing was 0·048 gram. All the strontium sulphate left unchanged was thus dissolved. Consequently Rose's method for separating barium from strontium and calcium, by boiling the solution of their salts with a solution containing potassium carbonate and sulphate, may be employed if this solution contains 1 part of the carbonate to 5 of the sulphate, for then any sulphate of strontium formed will pass into solution, and thus be separated from the barium sulphate produced at the same time. J. W.

Preparation of Pure Strontium Salts. By Barthe and Falières (*Bull. Soc. Chim.* [3], **7**, 104—108).—The authors have examined the various processes recommended for the preparation of pure strontium salts, and find that none of those previously described gives products free from barium or calcium. The process of precipitating the barium as chromate, boiling, filtering, and precipitating the filtrate with sodium carbonate gives a product which contains barium, as does also the carbonate obtained by the prolonged action of ammonium carbonate solution (10 per cent.) on impure precipitated strontium sulphate; the latter process is, however, the best of those examined. Barium was also detected in the product got by boiling impure precipitated strontium sulphate with a solution of potassium sulphate and carbonate. The addition of small quantities of alkaline sulphates to the hot or cold solutions of a strontium salt contaminated by barium gives the worst results of all the methods ordinarily employed; better results are obtained by fractional precipitation with dilute sulphuric acid (0·2 per cent.).

The authors give the following process for obtaining a pure

strontium salt from a barytostrontianite containing iron, aluminium, magnesium, calcium, and barium as impurities. The mineral, or the sulphide resulting from the reduction of the sulphate, is dissolved in such a quantity of hydrochloric acid (20 per cent.) as to leave a little undissolved. The aluminium and iron are precipitated by ammonia, filtered off, and excess of sulphuric acid added. The precipitate is washed first with dilute sulphuric acid (1—2 per cent.), and finally with water; it is thus freed from magnesium and calcium. It is now digested in the cold for some days with ammonium or potassium carbonate solution (10 per cent.), washed well, the residue treated with dilute hydrochloric acid, and the solution decanted; after remaining for 24 hours, this is filtered, and 200 grams of hydrochloric acid (sp. gr. 1·17) per litre are added to it, together with 2 or 3 grams of precipitated strontium sulphate, which may contain barium. After some hours, the solution is filtered, evaporated to dryness, dissolved in water, filtered, and crystallised. The spectrum given by the salt thus obtained shows strontium to be the only metal present. W. J. P.

Action of Hydrogen Peroxide on the Hydrated Oxides of Cadmium, Zinc, and Magnesium. By V. Kouriloff (*J. Russ. Chem. Soc.*, **22**, 171—194).—The author has made a careful investigation of this reaction, which has been studied by Thénard and others, but not hitherto elucidated. On heating the hydrated oxides of cadmium and zinc with a solution of hydrogen peroxide, basic peroxides have been obtained, which, on analysis, were found to have the formula $MO_2,M(OH)_2$. The above metals differ, therefore, in this point from the metals of the calcium group, which, under similar conditions, give products of the formula MO_2. The capacity of the metals for uniting with oxygen, as exemplified by the zinc and cadmium compounds, increases with the atomic weight, just as it does with the metals of the calcium group. The compounds obtained are very stable. They may be looked on as salts, in which the peroxides act as anhydrides like CO_2, SiO_2, &c., the hydrated monoxides as basic oxides. Thus these hitherto unisolated peroxides occupy an intermediate position between the acid peroxides CO_2, SiO_2, &c., and the neutral peroxides, SrO_2, BaO_2, &c.; and, like the peroxides MnO_3 and Mn_2O_7, although they do not exist in the free state, they yield stable compounds with other oxides. These compounds may also be regarded as hydrates of the formula $M(OH)_4$ of an oxide MO_3, in which a bivalent metal has taken the place of 2 atoms of hydrogen. These products are formed by direct addition of the oxygen of the hydrogen peroxide to the hydrated oxides of cadmium and zinc. The experiments on the magnesium compounds are incomplete. M. F.

Action of Nitric Acid on Metals. By C. Montemartini (*Gazzetta*, **22**, i, 250—265).—In the experiments described in this paper, the metals cadmium, iron, nickel, and cobalt were respectively dissolved in nitric acid of various degrees of concentration, at least 20 times the amount of acid required for solution being used so as to exclude secondary reactions as far as possible.

The experiments were principally carried out at a temperature of 8°, and the results are given in a series of tables. From these it appears that the evolution of ammonia is not limited to dilute solutions of nitric acid; thus, for instance, 0·00139 gram of ammonia was formed per gram of cadmium dissolved in 47 per cent. nitric acid; 0·0051 gram of ammonia per gram of iron dissolved in 52 per cent. nitric acid; and 0·01839 gram of ammonia per gram of cobalt dissolved in 42·8 per cent. nitric acid.

The gases evolved by the dissolution of 1 gram of the following metals in excess of 27·5 per cent. nitric acid were as follows:—

	NH_3.	HNO_2.	N_2O.	N.	NO.	Total grams.
Cadmium .	0·00197	0·00695	0·00570	0·00033	0·00216	0·01691
Iron	0·02493	0·00195	0·00422	0·00045	—	0·03553
Nickel	0·01874	0·00060	0·00749	0·00071	—	0·02754
Cobalt	0·02538	0·00077	0·00927	0·00467	—	0·04009

These numbers agree neither with the hypothesis that the dissolution of the metal is accompanied by the formation of nascent hydrogen, nor with that of the direct oxidation of the metal by the acid. No hydroxylamine is found amongst the final products of the reaction; this compound, if formed, must therefore be immediately destroyed by a secondary reaction. The nitric oxide is always of secondary origin, being derived in the case of cadmium, nickel, and cobalt from the decomposition of nitrous acid, and in the case of iron partly from the same source and partly from the oxidation of the ferrous salts first formed. In conclusion, the author holds that nitric acid acts as an oxidising agent in conjunction with the water present, the latter entering into the reaction. S. B. A. A.

Action of Nitric Acid on Zinc. By C. Montemartini (*Gazzetta*, **22**, i, 277—343).—The author has extended his investigations on the action of metals on nitric acid (preceding abstract) to zinc. The products formed in the reaction at a low temperature when the acid is in large excess are nitrous acid, hyponitrous acid, nitric oxide, nitric peroxide, nitrous oxide, nitrogen, and ammonia. Under the conditions mentioned, hydroxylamine is not found among the final products of the reaction, and free hydrogen is never evolved. With the exception of nitrous acid and nitric peroxide, the above products are formed, whatever the degree of concentration of the acid; no nitrous acid is, however, formed if the solution contains more than 30 per cent. of nitric acid, and no nitric peroxide if it contains less.

Ammonia.—At a temperature of 3—8°, the quantity in solution rises rapidly until the concentration of the acid is 10 per cent., then slowly until a maximum is attained between 40 and 45 per cent.; it falls abruptly at 47 per cent., and at 53 per cent. only a very small quantity is produced, which gradually diminishes with increased concentration, and may be represented by a straight line passing

through the zero point at 100 per cent. At a temperature of 85°, the maximum occurs at a concentration of 9 per cent., when it is equal to the production at the lower temperature; it then falls rapidly as the concentration is increased to 15 per cent.; beyond this point it may be represented by a line passing through the zero point when the concentration is 100 per cent.

Nitrous Acid.—At a temperature of 18—21°, the production increases rapidly with the temperature until a concentration of 14 per cent. of nitric acid is attained; it then falls with equal rapidity with increase of concentration to 30 per cent., at which stage nitrous acid ceases to appear among the final products.

Nitric Peroxide.—Between 18° and 22°, nitric peroxide is first formed at a concentration of 27 per cent. of acid; it increases slowly at first, rapidly between 64 per cent. and 72 per cent.; beyond 80 per cent. it remains almost constant.

Nitrous Oxide.—The formation of this compound takes place in comparatively large quantities and with great regularity. It reaches a maximum at a concentration of 40 per cent. acid and a minimum at 80 per cent.

Nitrogen is only formed in very small quantities in acid of all degrees of concentration.

The *velocity* of the dissolution of the zinc in nitric acid increases regularly with the concentration of the acid below 25 per cent.; it then falls slightly, remains constant between 33 per cent. and 42 per cent., then diminishes regularly, attaining its minimum value at a concentration of 68 per cent.; a considerable rise then takes place with increased concentration, but the previous maximum value is not again attained.

In conclusion, the author points out that the hypotheses that the reduction of nitric acid is effected by the direct action of zinc or by nascent hydrogen, both fail in certain cases, as a larger quantity of reduction products is formed than would be theoretically possible, and suggests that the water present enters into the reaction.

S. B. A. A.

The author in referring to previous researches makes no mention of those of Veley on the action of nitric acid on metals.—[Editors.]

A New Oxyiodide of Lead. By M. Gröger (*Monatsh.*, **13**, 510—515).—If a solution of 10 grams of iodine in 100 c.c. of absolute alcohol is mixed with one of 50 grams of crystallised lead acetate in 150 c.c. of water and 300 c.c. of absolute alcohol in a well-stoppered flask, allowed to remain at the ordinary temperature for 14—16 hours, and then filtered and mixed with 1 litre of distilled water, a brownish-red precipitate is formed, which has the composition PbO,PbI_2,I_2. The dry substance, which is brownish violet-red, is stable in dry air at the ordinary temperature, but when heated for a long time at 100°, or for a short time at 200°, loses iodine, and is converted into the basic lead iodide, PbO,PbI_2, of a chrome-yellow colour. When the original compound is treated with cold alcohol, the excess of iodine is not dissolved out, so that it must exist chemically combined; it is, however, dissolved out by a solution of potassium

iodide. Other reagents bring about a partial decomposition of the compound. C. F. B.

Specific Heat and Latent Heat of Fusion of Aluminium. By J. Pionchon (*Compt. rend.*, **115**, 162—165).—The experiments were made with commercial metal from Froges (Isère), containing 99·1 per cent. of aluminium, the rest being iron and silicon.

The amount of heat, q_t Cal., required to raise 1 gram of the metal from 0° to $t°$ is represented up to 580° by the equation—

$$q_t = 0{\cdot}393t - \frac{291{\cdot}86t}{1517{\cdot}8 + t},$$

and from 630° to 800° by the equation—

$$q_t = 0{\cdot}308t - 46{\cdot}9.$$

The specific heat thus rises slowly, but with increasing rapidity, from 0·2901 at 0° to 0·2894 at 550°; the specific heat of the molten metal at 650° is 0·308.

From the above data, the latent heat of fusion is 80 Cal. The value calculated from the modulus of elasticity $\left(7287\frac{kg}{mm^2}\right)$, by comparison with silver according to Person's formula, is 38·38 Cal.

Between 580° and the melting point, 625°, the metal assumes a granular structure, and becomes very friable, falling to powder on the slightest pressure. Jn. W.

Aluminium. By Balland (*Compt. rend.*, **114**, 1536—1538).—The author finds that air, water, wine, beer, cider, coffee, milk, oil, butter, fat, urine, saliva, earth, &c., have less action on aluminium than on copper, lead, zinc, or tin. It is attacked by vinegar and by salt, but not to an extent sufficient to interfere with its use for the construction of domestic utensils. The author's results are in direct contradiction with the statements of Lubbert and Roscher, and agree with the experiments of Lunge and Schmid. C. H. B.

Utilisation of Burnt Pyrites in the Manufacture of Iron Salts. By A. Buisine and P. Buisine (*Compt. rend.*, **115**, 51—53).—Burnt pyrites has hitherto been little used for the preparation of iron salts because of an erroneous belief that the action of acids is slow and incomplete. Burnt pyrites ground to a fine powder is slowly attacked in the cold by sulphuric acid of 50° to 66° B., but when mixed with the calculated quantity of acid and heated at a temperature not exceeding 300°, solution is rapid and complete. The composition of the product at various temperatures, when heating is continued until there is no further loss of weight, is given in the following table (p. 1282). If the temperature exceeds 300°, the proportion of basic salt in the product gradually increases.

Ferric sulphate can replace ferrous sulphate in many of its industrial applications, and is easily converted into the ferrous salt, if necessary, by the action of scrap iron on its solution.

	130°.	180°.	300°.
Water	20·63	8·41	0·00
Insoluble ferric oxide	11·75	7·38	2·74
Soluble ferric oxide	18·89	29·93	40·29
Total sulphuric acid	55·10	64·38	70·93
Free sulphuric acid	20·39	9·39	0·00
Normal ferric sulphate	47·23	74·82	96·65
Ferric oxide in excess of the normal sulphate	0·00	0·00	1·63

Ferric chloride is easily obtained by the action of gaseous hydrogen chloride on burnt pyrites in the cold. The gas from the salt-cake furnace may be led into a column filled with the pyrites. Heat is developed, and the product is almost pure. C. H. B.

Dissociation of Ferric Phosphate in presence of Water and of Saline Solutions. By B. Lachowicz (*Monatsh.*, **13**, 357—370).—Investigations of the different methods for preparing ferric phosphate have shown that a salt of the composition $FePO_4$ is only occasionally obtained, the precipitated compound usually yielding, on analysis, a larger or smaller percentage of phosphoric acid than that required by this formula. Such observations, as well as the fact that the white precipitate, if left in contact with water, becomes brownish, indicate that water is in all probability able to decompose the phosphate.

The author now finds that the precipitate, containing 64·41 per cent. of PO_4 (PO_4 for $FePO_4$ = 62·91 per cent.), obtained on adding disodium hydrogen phosphate to a hot solution of ferric chloride, sufficient ammonia being present to keep the solution neutral, is only very sparingly soluble in water, but is rapidly decomposed by it. The quantity of salt decomposed by the water at any particular temperature depends on the amount of water present, and the decomposition does not proceed beyond a fixed limit, unless the phosphoric acid which has entered into solution is removed from the sphere of action. In presence of a large excess of water, the whole of the phosphoric acid is eventually withdrawn from the iron phosphate.

The presence of saline substances induces a modification in the action of water on ferric phosphate. One class of salts promotes the decomposition, another retards it, whilst a third merely acts as a solvent. Solutions of salts having an alkaline reaction have a much more powerful decomposing effect, whilst sulphates have only a slightly stronger action than pure water. The chlorides of the alkali metals appear to diminish the decomposing action of water, and cause it to behave more as a solvent towards the phosphate. Humic acid, prepared according to Mulder's instructions (*Annalen*, **36**, 243), acts on ferric phosphate as a solvent, but the greater portion of the phosphoric acid which enters into solution seems to be separated by the further decomposing action of the organic acid. G. T. M.

Nickel and Cobalt. By C. Lepierre and Lachaud (*Compt. rend.*, **115**, 115—117).—When anhydrous nickel sulphate, or the oxide,

hydroxide, or carbonate, is heated with five or six times its weight of fused ammonium sulphate, the compound $3NiSO_4,2Am_2SO_4$ separates in deep-yellow tetrahedra and cubotetrahedra, which can be rapidly washed with a small quantity of water followed by strong alcohol. In contact with water, the crystals soon become hydrated, with great development of heat.

If the preceding salt is heated in presence of ammonium sulphate, it is converted into regular octahedra of the anhydrous nickel sulphate described by Klobb; it has a canary-yellow colour, hydrates gradually in contact with water, and is insoluble in strong alcohol; sp. gr. at 20° = 3·67.

When ammonium hydrogen sulphate is employed instead of the normal salt, the nickel sulphate forms fusiform prismatic crystals, the difference being due to the presence of about 0·5 per cent. of free sulphuric acid.

The double ammonium nickel sulphate when strongly heated yields amorphous nickel oxide, but the anhydrous nickel sulphate, whether fusiform or octahedral, yields nickel oxide with the same form as the original crystals.

Cobalt sulphate behaves in a precisely similar manner, and yields a double salt with ammonium sulphate. The anhydrous sulphate occurs in both the octahedral and fusiform modifications, the difference being due to the same cause as in the case of nickel sulphate.

C. H. B.

Permolybdic Acid. By E. Péchard (*Compt. rend.*, **114**, 1481—1483).—Permolybdic acid is isolated either by decomposing the barium salt with sulphuric acid, by heating the hydrated molybdic acid, $MoO_3,2H_2O$, with a solution of hydrogen peroxide, or by the action of hydrogen peroxide on metallic molybdenum or on the blue oxide. If the solution obtained by one of these methods is evaporated in a vacuum at the ordinary temperature, it yields a yellow, crystalline powder soluble in water. The solution can be boiled without undergoing decomposition; it is not affected by strong acids, with the exception of hydrochloric acid, which reduces it to molybdic acid with evolution of chlorine. Reducing agents, such as stannous chloride and ferrous sulphate, yield first molybdic acid and afterwards the blue oxide.

Crystallised permolybdic acid has the composition $Mo_2O_7,5H_2O$. At 100° it loses $4H_2O$, and at a higher temperature it simultaneously loses both the remaining water, and also oxygen. From the composition of the permolybdates (Abstr., 1891, 988), it seems that permolybdic acid is monobasic, and hence the formula of the crystallised acid is $HMoO_4 + 2H_2O$.

When the formation of permolybdic acid is used as a test for hydrogen peroxide (Denigès), it is better to acidify with sulphuric acid than with citric acid as recommended by Crismer. Citric acid reduces permolybdic acid.

C. H. B.

Nitrogen Compounds of Platinum. By M. Vèzes (*Compt. rend.*, **115**, 44—45).—This paper contains a summary of the author's investigations of these compounds. *Potassium platomonochloronitrite*,

$Pt(NO_2)_3ClK_2 + 2H_2O$, obtained by the regulated action of hydrochloric acid on the platonitrite, is very stable in solution, and crystallises in very soluble, brilliant, pale-yellow plates. *Potassium platodichloronitrite*, $Pt(NO_2)_2Cl_2K_2$, obtained by the action of hydrochloric acid on the platonitrite, crystallises in very soluble, golden-yellow, monoclinic needles. It is the most important member of the chlorine series, because of its great stability in solution and the fact that it is constantly formed in all reactions that can give rise to nitrochloro-derivatives. *Potassium platidichloronitrite*, $Pt(NO_2)_4Cl_2K_2$, was described previously under the name *platichloronitrite*. *Potassium platitrichloronitrite*, $Pt(NO_2)_3Cl_3K_2$, is obtained by the regulated action of chlorine water on the platomonochloronitrite. It crystallises in very soluble yellow prisms, and is stable in solution. *Potassium platipentachloronitrite*, $Pt(NO_2)Cl_5K_2 + H_2O$, was previously described as a nitrosochloroplatinate, and the formula $Pt(NO)Cl_5K_2 + H_2O$ was attributed to it.

Potassium platomonobromonitrite, $Pt(NO_2)_3BrK_2$, is obtained by the regulated action of hydrobromic acid on the platonitrite. It is very stable in solution, and crystallises in very soluble, brilliant, pale-yellow plates, isomorphous with the *platomonochloronitrite*. *Potassium platodibromonitrite*, $Pt(NO_2)_2Br_2K_2 + H_2O$, was described previously under the name platobromonitrite (Abstr., 1891, 807), and the *platidibromonitrite*, $Pt(NO_2)_4Br_2K_2$ was described under the name *platibromonitrite*. *Potassium platitribromonitrite*, $Pt(NO_2)_3Br_3K_2$, was described in a previous paper as platibromonitrosonitrite, and the formula $Pt(NO)(NO_2)_2Br_3K_3$, was erroneously attributed to it. *Potassium platitetrabromonitrite*, $Pt(NO_2)_2Br_4K_2$, is obtained by the regulated action of bromine on the platonitrite; it forms red prisms which dissolve in water with partial decomposition into platinobromide, platodibromonitrite, and nitrogen oxides.

The iodine compounds are *potassium platodiiodonitrite*, $Pt(NO_2)_2I_2K_2 + 2H_2O$, described by Nilson under the name "platoiodonitrite;" *potassium platitetraiodonitrite*, $Pt(NO_2)_2I_4K_2$, previously described by the author; and *potassium platipentaiodonitrite*, $Pt(NO_2)I_5K_2$, described in a former paper under the name "nitrosoiodoplatinate," with the erroneous formula $Pt(NO)I_2K_2$.

These salts represent the following types, X being any halogen:— $Pt(NO_2)_4K_2$, $Pt(NO_2)_3XK_2$, $Pt(NO_2)_2X_2K_2$, PtX_4K_2, $Pt(NO_2)_4X_2K_2$, $Pt(NO_2)_3X_3K_2$, $Pt(NO_2)_2X_4K_2$, $Pt(NO_2)X_5K_2$, and PtX_6K_2.

C. H. B.

Chlorazopalladium Compounds. By M. Vèzes (*Compt. rend.*, **115**, 111—113).—*Potassium pallaiiochloronitrite*, $Pd(NO_2)_2Cl_2K_2$, analogous to the platinum compound, is easily obtained (1) by the regulated action of hydrochloric acid on potassium palladionitrite; (2) by the action of potassium nitrite on potassium palladiochloride; and (3) by the action of potassium palladiochloride on an equivalent proportion of potassium palladionitrite. It forms brownish-yellow, dichroic, monoclinic prisms of 123° 41′; $a:b:c = 0{\cdot}55041:1:0{\cdot}60334$; $\beta = 76°\ 31{\cdot}5'$. The salt dissolves in three times its weight of cold water and twice its weight of hot water, and

is very stable in solution, but when boiled with excess of chlorine or hydrochloric acid it is converted into the palladiochloride, with evolution of nitrogen oxides. The decomposition is not complete, however, until the salt has been repeatedly evaporated to dryness with the acid. An excess of potassium nitrite, on the other hand, converts the salt, on boiling, into the palladionitrite.

When dried in the air at the ordinary temperature, the crystals remain unaltered and they do not lose water at 100°. At a dull red heat nitrogen oxides are evolved, and a residue of potassium chloride and palladium is left. C. H. B.

Phosphopalladious Compounds. By E. Fink (*Compt. rend.*, **115**, 176—177).—A series of compounds analogous to Schützenberger's phosphoplatinous compounds.

Phosphopalladious chloride, $PCl_3,PdCl_2$, is prepared by heating dry, finely-divided palladium (1 atom) with phosphoric chloride (1 mol.) at 250—280° for an hour. The reddish-brown product, on recrystallisation from benzene, yields brown needles of the chloride. Phosphopalladious chloride is unstable in the air, and is decomposed by water into hydrogen chloride and an *acid* $P(OH)_3,PdCl_2$, which is obtained in yellowish-red, deliquescent crystals on evaporating the solution in a vacuum. Methyl and ethyl alcohols have a similar action, the corresponding *ethereal salts* being formed; these may be recrystallised from benzene. Phosphopalladious chloride combines in molecular proportions with phosphorous chloride; the compound crystallises from benzene in yellow, silky needles, is unstable in air, and is decomposed by water into hydrogen chloride and an acid which is under investigation. Jn. W.

Removal of Platinum from Iridium. By U. Antony (*Gazzetta*, **22**, i, 275—276).—To obtain pure iridium, the author takes metallic iridium precipitated by zinc from an acid solution of iridic chloride, treats it first with strong nitric acid (sp. gr. = 1·35) containing nitrous acid, to eliminate osmium and palladium, then repeatedly with weak aqua regia (1 part HNO_3; 3 parts HCl; 3 parts H_2O) to dissolve the platinum and any traces of osmium and palladium, washes the residues, and fuses with potassium hydrogen sulphate to remove rhodium. The insoluble iridic oxide left is reduced by hydrogen in the cold, the metal converted into potassium chloriridate, and purified by repeated crystallisation. The metal obtained in this way still contains platinum, but on passing a current of chlorine and carbon monoxide over it at a temperature of 250°, a small quantity of yellow crystals sublime, which when treated with water evolve carbonic anhydride and hydrogen chloride, and leave a black powder consisting of platinum. The iridium is left as a dark-green powder containing iridium and chlorine, and is entirely free from platinum. S. B. A. A.

Mineralogical Chemistry.

Glauber's Salt in the Potash Mines of Kalusz. By R. Zaloziecki (*Monatsh.*, **13**, 504—509).—Crystals of Glauber's salt, $Na_2SO_4 + 10H_2O$, having been discovered in a cleft of the kainite layer in the mines of Kalusz, Galicia, and the superincumbent strata being found to contain no sodium sulphate, but only sodium chloride, it was supposed that the above mentioned Glauber's salt had been formed by the action of the rain water percolating through the upper strata, where it dissolved sodium chloride, and then penetrating to the kainite layer, where the sodium sulphate is formed by the reaction between sodium chloride and the potassium sulphate of the kainite. This view was confirmed by a laboratory experiment. A 10 per cent. solution of sodium chloride was slowly filtered through a tube 30 cm. long, packed with powdered kainite, and the filtrate collected in four separate portions. The second of these deposited crystals of $Na_2SO_4 + 7H_2O$, when allowed to stand in the air, and the third crystals of $Na_2SO_4 + 10H_2O$, when concentrated on the water bath. The fourth fraction and the residue in the tube also contained sodium sulphate. It was further observed that when a solution containing calcium sulphate and much sodium sulphate is evaporated, the main portion of the calcium sulphate does not separate out until a large quantity of the sodium sulphate has crystallised. C. F. B.

Artificial Formation of Potassium Nepheline. By A. Dubois (*Compt. rend.*, **115**, 56—57).—A small quantity of potassium hydrogen fluoride is heated in a platinum crucible at first slowly and afterwards nearly to pale redness, and a small quantity of alumina is added, its solution being brought about by the addition of silica or potassium silicofluoride. The temperature of the crucible is kept constant for 15 hours, and it is then allowed to cool slowly. On treatment with water, a homogeneous and well crystallised product is left, which has the composition of potassium-nepheline,

$$K_2O,Al_2O_3,2SiO_2.$$

It forms rhombic prisms which differ entirely from sodium-nepheline in their crystalline symmetry. The prism is almost equally developed in all directions, and its angle is about 97°; it has a truncating face g' (010). The plane of the optical axes is parallel to g', and their separation is about 40°; the acute bisectrix perpendicular to p (001) is negative, and the birefractive maxima

$$N_g - N_p = 0{\cdot}008,\ N_g - N_m = 0{\cdot}002,\ \text{and}\ N_m - N_p = 0{\cdot}006.$$

The crystals, which behave like aragonite, and group themselves in pseudo-hexagonal prisms, have a marked tendency towards hexagonal symmetry. C. H. B.

Water from the Arctic Ocean. By J. Thoulet (*Compt. rend.*, **114**, 1547—1549).—Two specimens were collected at the surface in the year 1891, and the sp. gr. and the nature and amount of the suspended matter were determined.

The first specimen was collected in lat. 68° 33′ N., and long. 12° 55′ N.W. of Paris, the depth of the sea at that point being 2048 metres, the surface temperature 6·2° and the temperature of the air 6°; sp. gr. at 6·2° compared with water at 4° = 1·0261, at 15·3° compared with water at 4° = 1·0245, and at 17·5° compared with water at 17·5° = 1·0253. The quantity of organic matter in suspension was 0·97 milligram, and of inorganic matter 0·24 milligram per litre. The latter consisted partly of rounded grains of quartz, with some mica and chalcedony.

The other specimen was collected in lat. 62° 7′ N. and long. 1° 43′ N.W. of Paris, the depth being 400 metres, and the surface temperature 12°; sp. gr. at 12° compared with water at 4° = 1·0269, at 14·2° compared with water at 4° = 1·0264, and at 17·5° compared with water at the same temperature = 1·0269. The suspended organic matter was 2·14 milligrams, and the suspended inorganic matter 0·63 milligram per litre.

The author discusses the bearing of these results on the question of ocean currents. C. H. B.

Aluminium in Mineral Waters. By F. Parmentier (*Compt. rend.*, **115**, 125—126).—The following table gives the quantity of aluminium oxide per litre in various springs:—

1.	2.	3.	4.	5.	6.	7.	8.
0·008	0·007	0·006	0·004	0·003	0·015	0·010	0·006

9.	10.	11.	12.	13.
0·001	0·014	0·006	0·002	0·009

(1) Frobert, (2) Saint Louis, No. 1, (3) Précieuse, (4) Jeanne d'Arc, (5) Sévigné, all at Vichy Saint-Yorre; (6) Dubois, (7) Vincent, both at Vichy; (8) Bayard, (9) Amélie d'Hauterive, both at Hauterive; (10) Grande Source, (11) Jeanne d'Arc, (12) Saint-Léon, all at Pougues-les-Eaux; (13) Yvonne, at Chatelguyon.

The author also detected aluminium in many cases where its presence is not recorded in previous analyses of the same springs. The precipitated alumina often contains traces of rare metals.

C. H. B.

The Mineral Water of "Monte di Malo." By P. Spica (*Gazzetta*, **22**, i, 354—371).—Chalybeate sulphuretted mineral waters containing silica, lime, manganese, and traces of arsenic arise from the side of the "Monte di Malo" (Vicenza). The water has an almost constant temperature of 15·6°. It is limpid, faintly yellowish in colour, has a slight sulphurous odour, and a pleasant taste. Its reaction is slightly acid at first, but soon becomes slightly alkaline. Its composition is as follows:—

Substances dissolved in 1 *litre at* 15·6°.

Oxygen	0·37	c.c.
Nitrogen	17·15	„
Hydrogen sulphide	1·55	„
Free carbonic anhydride	73·83	„
Carbonic anhydride (partially combined)	0·0455	gram.
„ (combined)	0·0455	„
Total residue at 110°	0·1363	„
„ at 180°	0·1265	„
Silica	0·0218	„
Titanic acid (?)	0·00103	„
Chlorine	0·000453	„
Sulphuric anhydride	0·000236	„
Phosphoric anhydride	0·002257	„
Arsenious anhydride	0·000063	„
Copper oxide	traces	
Ferric oxide	0·00798	„
Alumina	0·000836	„
Manganous oxide	0·001172	„
Baryta	traces	
Lime	0·025625	„
Magnesia	0·011338	„
Potash	0·000562	„
Soda	0·012174	„
Vanadic acid (?)	traces	

The water is entirely free from ammoniacal and nitrous compounds, but contains a little organic matter, probably of vegetable origin, which requires for its oxidation a quantity of permanganate equivalent to 0·00144 gram of oxygen per litre of water. S. B. A. A.

Alteration of Chalybeate Mineral Waters. By J. Riban (*Compt. rend.*, **114**, 1483—1485).—Some time ago the author estimated the quantity of iron held in solution in various bottled mineral waters, as sold by pharmacists. His results are given in the following table, together with the quantity of iron per litre originally in solution when the water issued from the spring:—

	1.	2.	3.	4.	5.	6.
In solution as protoxide	0·0007	0·0000	0·0000	0·0002	—	0·0000
Total iron in solution	0·0022	0·0007	0·0007	0·0010	0·0059	0·0011
Iron originally in solution	0·0809	0·0082 0·0041	0·0521	0·0171	0·0050	0·0615

	7.	8.	9.	10.	11.	12.	13.
In solution as protoxide ..	0·0000	0·0004	0·0000	0·0255	0·0002	0·0002	0·0004
Total iron in solution ...	0·0004	0·0015	0·0000	0·0260	0·0015	0·0013	0·0011
Iron originally in solution..	0·0618	0·0072 0·0021	0·0112	0·0448	?	?	0·0073

(1) Auteuil; (2) Bussang, the two numbers given for the original quantity of iron being by two different authorities; (3) Forges (Royale); (4) Forges (Reinette); (5) Lamalou (Bourges); (6) Orezza (Sorgenta sottana); (7) the same; (8) Pougues (Saint Légér), the two numbers for the total iron being from two authorities; (9) Soultzbach; (10) Spa (Pouhon); (11) Vals (Rigolette); (12) Vals (Dominique); (13) Vichy (Lardy). C. H. B.

Chalybeate Mineral Waters. By F. Parmentier (*Compt. rend*, **115**, 53—55).—The author quotes analyses which show that chalybeate waters retain a considerable quantity of iron in solution, if bottled whilst they contain carbonic anhydride (compare Riban, preceding abstract). C. H. B.

Chalybeate Mineral Waters. By J. Riban (*Compt. rend.*, **115**, 185).—A reply to Parmentier (preceding abstract).

Organic Chemistry.

Affinity Coefficients of Alkyl Iodides and Bromides. By N. Menschutkin and M. Vasileff (*J. Russ. Chem. Soc.*, **22**, 346—358; also *Zeit. physikal. Chem.*, **5**, 589—600).—The rates at which alkyl iodides or bromides combine directly with organic amines give a measure of the affinity of both these classes of substances. In this paper, the authors communicate the results of their investigations of the rate of combination of the iodides and bromides of the alcohol radicles with triethylamine. The alkyl chlorides do not unite with triethylamine under the conditions of experiment chosen by the authors. Triethylamine and the alkyl halides were mixed in molecular proportions, and 1 vol. of the mixture was diluted with 15 vols. of acetone or of benzene. Small glass tubes were filled with weighed quantities of this mixture, and these were immersed for a definite time in a thermostat at 100°. On being taken out, they were rapidly cooled with ice-water, and the quantity of the bromide or iodide of the ammonium base they contained was at once determined, after neutralisation with dilute nitric acid, by titration with silver nitrate

solution, potassium chromate being used as indicator. The results with iodides were not quite sharp, as the combination goes on in aqueous solution, even at the ordinary temperature. From the observed times and the titres, the coefficient of velocity of the reaction was calculated by the usual formula.

In acetone solution, the combination proceeds about 10 times as fast as in benzene solution, and the coefficients of velocity of the iodides are from six to seven times as great as those of the corresponding bromides. The coefficients diminish as the molecular weight of the normal alkyls increases, and are greater for normal than for iso-alkyls. The following table contains the numerical values of the coefficient of velocity, k:—

	Iodides.		Bromides in acetone.
	In benzene.	In acetone.	
Methyl	0·665	—	—

Isopropyl	—	0·00121	—
Normal butyl	—	0·00832	0·00123
Isobutyl	—	0·00191	0·000252
Normal heptyl	—	0·00653	0·00119
Normal octyl	—	0·00602	0·00110

The ratios of the coefficients of the alkyls agree well with those obtained by Conrad and Hecht from the action of sodium ethoxide and alkyl iodide at 24°. J. W.

Action of Methyl Iodide and of Chloroform on Nitroisopropane. By I. Kisel (*J. Russ. Chem. Soc.*, **22**, 380—383).—Caustic soda (2 mols.) dissolved in alcohol was added to nitroisopropane (1 mol.), and the sodium compound thus obtained was heated with methyl iodide (3 mols.) in a sealed tube at 110° for two hours. Sodium iodide and small quantities of a hygroscopic substance separated out from the alcoholic solution on cooling. On distilling the liquid portion, alcohol passed over, together with excess of methyl iodide and two liquids of unknown composition. The solid residue was treated with strong caustic soda and the solution distilled. Propylamine and ammonia came over, with another base, whose chloride could not be crystallised. From the mother liquor from which ammonium and propylammonium chloride were crystallised, two different sorts of crystals (nodules and plates) were obtained by evaporation in a vacuum and recrystallisation from cold alcohol. The substance forming nodular masses contained a quantity of chlorine corresponding with the formula NHMe·OH,HCl.

When chloroform was employed instead of methyl iodide, a substance was obtained which crystallised in rhombic plates, was easily

soluble in alcohol and ether, and had approximately the composition $C_3H_6NO_2$. Aldehyde was observed among the products when ethyl iodide was used. J. W.

Polymerides of Dichloracetonitrile and Trichloracetonitrile. By N. Tscherven-Iwanoff (*J. pr. Chem.* [2], **46**, 142—151; compare Abstr., 1886, 323; 1891, 1332).—Dihydroxyperchloromethylcyanidine (Abstr., 1891, 1332) crystallises in needles, melts at 152—153°, and dissolves easily in water, sparingly in glacial acetic acid, but not in the other usual solvents; it forms unstable salts. Amidodimethylcyanidine (*loc. cit.*) dissolves easily in water and glacial acetic acid, but not in alcohol or ether.

Dichloracetonitrile is polymerised somewhat more easily by hydrogen bromide than by hydrogen chloride (Abstr., 1885, 739); its *hydrochloride* melts with decomposition at 140—145°, and is converted into the polymeride and hydrogen chloride when heated in a sealed tube at 130—140°. As hydrogen iodide acts on these nitriles, it cannot be used for their polymerisation.

Determinations of the molecular weights of these polymerides by Raoult's method give results which agree with the formulæ $(CCl_3{\cdot}CN)_3$ and $(CHCl_2{\cdot}CN)_2$ respectively. A. G. B.

Carbon Diiodide. By H. Moissan (*Compt. rend.*, **115**, 152—155).—When carbon tetriodide, CI_4 (Abstr., 1891, 1420), is exposed in a vacuum to the sun's rays, or even to diffused daylight, or to a temperature of 120°, it splits up into iodine and carbon diiodide, C_2I_4. The diiodide is, however, best prepared by gradually adding the theoretical quantity of powdered silver to a cooled solution of the tetriodide in carbon tetrachloride (or bisulphide), then sealing up the tube, and allowing the reaction to proceed in the cold until the red colour of the tetriodide has changed to the yellow colour of the diiodide. Excess of silver at a higher temperature (50°) causes the complete reduction of the tetriodide. The solution of the diiodide is then separated from the silver iodide, the solvent distilled off on the water-bath, the residue allowed to crystallise, and the crystals purified, either by recrystallisation, or by sublimation in a vacuum.

Carbon diiodide crystallises from carbon tetrachloride in brilliant, pale yellow needles, and from boiling alcohol in small, brilliant prisms. It melts at 185°, volatilises without decomposition at a slightly higher temperature, but begins to decompose at 200°. Its sp. gr. is 4·38. It is very soluble in carbon tetrachloride, carbon bisulphide, ether, and boiling alcohol, but only sparingly in cold alcohol. It is not reduced by hydrogen, even at 200°, and is not attacked by chlorine or bromine in the cold, although at higher temperatures these effect a partial substitution of the iodine. When heated in oxygen, it melts, and then splits up into its elements, the carbon burning to carbonic anhydride. It is not attacked by sulphur below 110°, but at that temperature the iodine is displaced by sulphur, carbon bisulphide being formed. Phosphorus attacks it at a temperature somewhat above the melting point of that element. It is not acted on by weak boiling solutions of potassium permanganate or

chromic acid, or by boiling nitric acid, although it is completely oxidised by the latter at 180°. It is decomposed by sulphuric acid at 250°, but not by hydrochloric or hydriodic acid. It is not affected by boiling aqueous potash, but is decomposed into iodoform, iodine, and potassium carbonate by fusion with solid potash. Silver fluoride does not act on a solution of the iodide in carbon tetrachloride.

Jn. W.

Action of Chlorine on Isobutyl Alcohol. By A. Brochet (*Compt. rend.*, **114**, 1538—1541).—When isobutyl alcohol is treated with a current of dry chlorine, there is at first considerable development of heat, but after a time the reaction slackens and the liquid must be gently heated. No isobutyl chloride is formed, and the product can be separated into two fractions, boiling respectively at 80—100° and 170—250°. The examination of the latter is not yet complete; the former consists of *chlorisobutaldehyde*, $CMe_2Cl{\cdot}COH$. It boils at 90—91°, and has an odour recalling that of chloral, and a piquant, bitter taste; sp. gr. at 15°, compared with water at 4°, = 1·086. It reduces Fehling's solution and ammoniacal silver nitrate, combines with sodium hydrogen sulphite to form a crystalline compound, and, when oxidised with dilute alkaline permanganate, yields acetone and hydroxyisobutyric acid,

$$CMe_2(OH){\cdot}COOH,$$

melting at 78°.

Chlorisobutaldehyde does not solidify at −20°, and yields no hydrate at this temperature. When agitated for a short time with its own volume of concentrated sulphuric acid, it forms slender needles, which can be purified by washing, followed by distillation in water vapour. This product is further purified by solution in acetic acid, precipitation with water, and redistillation. It forms white, odourless, tasteless needles, which melt at 107°, sublime at 110°, and are volatile in water vapour, even below 100°. This compound is a polymeride of monochlorisobutaldehyde, and the freezing point of its acetic acid solution shows that it has the formula $C_{12}H_{21}Cl_3O_3$. It is soluble in ether, alcohol, acetic acid, benzene, &c., and crystallises from ether in monoclinic prisms; it reduces Fehling's solution and ammoniacal silver nitrate distinctly, although with some difficulty.

C. H. B.

Pentamethylene Glycol and its Oxides. By N. Demyanoff (*J. Russ. Chem. Soc.*, **22**, 388—391).—Pentamethylene glycol is a thick liquid with a burning taste, and does not solidify in a mixture of snow and salt. It mixes freely with water and alcohol, but is only soluble with difficulty in ether. At a pressure of 31 mm., it distils at 162°. Its density is $d\ 0°/0° = 1·0041$; and its vapour density corresponds with the formula $C_5H_{12}O_2$. When heated with three times its volume of 60 per cent. sulphuric acid in a sealed tube at 100° for 1½ hours, it became brown, and a quantity of tarry matter was formed; the product, diluted with its own bulk of water, and distilled on the water bath, yielded a distillate which separated into two layers. After neutralisation of the whole with potash, the upper

layer was separated and dried with fused caustic potash. On a first distillation, it boiled between 79° and 83°; on refractionation, it came over between 80° and 81°. The product is a light, colourless, mobile liquid, with an odour resembling that of ethyl ether. Analyses and vapour density determinations agree with the formula $C_5H_{10}O$. It is, therefore, the anhydride of pentamethylene glycol. Its density at $0°/0° = 0{\cdot}8800$, and in its properties it is very similar to the isomeric oxide of γ-pentylene glycol. It is more soluble in cold than in boiling water, and is miscible with alcohol and ether. It does not combine with water, even on heating the two together at 200°, but it unites readily at 100° with fuming hydrobromic acid. Neither silver nitrate in ammoniacal solution, nor Fehling's solution, is reduced by it. Hydroxylamine has no action on it. Its formula is probably

$$\begin{array}{l} CH_2{\cdot}CH_2{\cdot}O \\ | \quad\quad | \\ CH_2{\cdot}CH_2{\cdot}CH_2 \end{array}$$

J. W.

Action of Zinc Dust and Alcohol on Chlor-α-dibromhydrin. By G. Gustavson (*J. pr. Chem.* [2], **46**, 157—160; compare Abstr., 1891, 159, 888).—The chlor-α-dibromhydrin was dissolved in alcohol, and the solution dropped on to the zinc kept at 90° in an apparatus from which both gaseous and liquid products could be collected. These were recognised as consisting almost entirely of propylene and allyl chloride. The former is frequently formed by the action of zinc dust and alcohol on halogen glycerol derivatives; the latter is regarded by the author as being evidence that chlorotrimethylene is the first product of the reaction. In support of this point, he adduces the conversion of chlorotrimethylene into allyl acetate, by the action of potassium acetate and acetic acid.

A. G. B.

Action of Acetic Anhydride on Glucose. By Istrati and Edeleanu (*Chem. Centr.*, 1892, i, 624; from *Bull. Soc. Sci. Fiz. Bucuresci*, **1**, 46).—According to the authors, V. Meyer's aldehyde formula, $OH{\cdot}CH_2{\cdot}[CH{\cdot}OH]_4{\cdot}COH$, for glucose, cannot be correct, because no unsaturated hexabasic acid is obtained when this sugar is heated with acetic anhydride for several days, the only product of the reaction being the tetracetyl derivative. A. G. B.

Sugar from Linseed. By R. W. Bauer (*Landw. Versuchs-Stat.*, **40**, 480).—Crude linseed mucilage, which had been treated with alcohol and ether, was boiled with dilute sulphuric acid, and the filtrate treated with chalk, evaporated down, and extracted with alcohol. The sugar so obtained is dextrorotatory, $[\alpha]_D = +46{\cdot}135°$. The phenylhydrazine reaction gave a slightly lævorotatory yellow solution, and needles of the dextrosazone melting at 204°. N. H. M.

Isomaltose. By C. J. Lintner (*Chem. Centr.*, 1892, i, 623; from *Woch. Brauerei*, **9**, 245—247).—The author replies to some criticisms passed by the *Brewing Trade Review*, **6**, 52, on his isomaltose. The assertion, made in the Review in question, that the substance termed isomaltose by E. Fischer and others is identical with the substance formerly called gallisin, the author says, is incorrect. Moreover, gal-

lisin must be expunged from chemical literature. The preparation of the osazone of the author's isomaltose proves, beyond a doubt, the identity of this substance with Fischer's isomaltose. Moreover, he believes that the maltodextrin theory of Brown and Morris (Trans., 1885, 570) is not tenable; the transformation products of starch are by no means so numerous as they make out, and are probably limited to three, namely, dextrin, isomaltose, and maltose. The author's method for isolating isomaltose will be divulged later; it differs from that employed by Brown and Morris for preparing maltose.

A. G. B.

Precipitation of Raffinose by Ammoniacal Lead Acetate. By T. Koydl (*Chem. Centr.*, 1892, i, 653—654; from *Österr.-ungar. Zeit. Zuck.-ind.*, **21**, 92—93).—The author has previously shown that although ammoniacal lead acetate is a good qualitative precipitant for raffinose, it is of no use for quantitative separation, inasmuch as the precipitation is never complete. Weisberg having maintained that quantitative separation is possible by means of this reagent, the author adduces new experiments to prove that Weisberg is in error.

A. G. B.

Vegetable Cholesterol. By Gérard (*Compt. rend.*, **114**, 1544—1546).—The cholesterol derived from phanerogamous plants is identical in physical and chemical properties with the phytosterin of Hesse, whilst that derived from cryptogams gives the same reactions as the ergosterin of Tanret.

In order to obtain a pure product, the crude material is treated with dry ether, the residue from the distillation of the ethereal solution is saponified with alcoholic potash, and the soap is dried and extracted with ether. The ethereal solution, on evaporation, deposits acicular crystals which are purified by further treatment with potash. The whole is then dissolved in water, and the strongly alkaline liquid is agitated with chloroform, when the cholesterol separates in almost pure crystals. Final purification is effected by converting the cholesterol into the benzoate, crystallising the latter repeatedly from alcohol, and saponifying.

Cholesterol from the higher plants has the following melting points and rotatory power:—

	Rotatory power.	Melting point.
Dried in a vacuum....	$\alpha_0 = -34{\cdot}4°$	132—133°
Dried at 100°	$\alpha_0 = -36{\cdot}5°$	135°

The numbers are identical with those obtained by Hesse for phytosterin. Although the cholesterols from lower vegetables all give the reactions of ergosterin, the melting point and rotatory power vary in some cases:—

	Rotatory power.	Melting point.
From *Penicillium glaucum*, dried at 100°	$\alpha_D = -143{\cdot}3°$	135·0°
„ *Æthalium septicum*, dried at 100°	$\alpha_D = -28{\cdot}0°$	134·5°

C. H. B.

Action of Propyl Iodide on Trimethylamine. Trimethylpropylammonium Iodide. By H. Malbot and A. Malbot (*Bull. Soc. Chim* [3], **7**, 136).—Trimethylamine in aqueous solution is

allowed to act in molecular proportion on propyl iodide for 18 hours; the action is complete when a little of the product poured into potash gives a precipitate which melts on heating the solution, solidifies again on cooling, and dissolves on dilution. The main bulk of the product is evaporated to dryness to expel trimethylamine, taken up with water, the solution shaken with the calculated quantity of silver oxide, and filtered. After concentrating and adding hydrochloric acid and platinum tetrachloride, the solution yields *trimethylpropylammonium platinochloride*, which may be crystallised from water, and is very stable towards heat. W. J. P.

Action of Isopropyl Iodide on Trimethylamine. Trimethylisopropylammonium Iodide. By H. Malbot and A. Malbot (*Bull. Soc. Chim.* [3], **7**, 136—138).—The action of isopropyl iodide on trimethylamine is exactly similar to that of the normal iodide (see preceding abstract). The reaction is completed after five days' contact in the cold, and only proceeds a little more rapidly at 100°; a small quantity of propylene is liberated, probably owing to the presence of a little propylene iodide. *Trimethylisopropylammonium iodide* is thus obtained in beautiful crystals which are more soluble than those of the corresponding normal propyl derivative. The *platinochloride* crystallises in long, red, hydrated prisms which lose water in the desiccator. W. J. P.

Action of Allyl Iodide on Trimethylamine. Trimethylallylammonium Iodide. By H. Malbot and A. Malbot (*Bull. Soc. Chim.* [3], **7**, 138—139).—The reaction between trimethylamine and allyl iodide is very violent, slight explosions occurring as the amine falls, drop by drop, into the iodide. *Trimethylallylammonium iodide* is isolated in a similar manner to the corresponding compounds already described by the authors (see preceding abstracts). The *platinochloride* is very stable towards heat. W. J. P.

Nitroguanidine and Amidoguanidine. By J. Thiele (*Annalen*, **270**, 1—63).—The author's experiments have shown that Jousselin's "nitrosoguanidine" (Abstr., 1878, 132; 1879, 613 and 914) is in reality nitroguanidine, and that its constitution is most probably represented by the formula $NO_2{\cdot}NH{\cdot}C(NH){\cdot}NH_2$ (compare Pellizzari, this vol., p. 579).

Nitroguanidine melts at 230° with evolution of ammonia, and is soluble in 372 to 375 parts of water at 19·3°, and in about 11 parts of boiling water. The *silver* derivative, $CH_3N_4O_2Ag$, is precipitated when barium hydroxide is gradually added to a warm aqueous solution containing nitroguanidine and silver nitrate in molecular proportion; it is a colourless compound, almost insoluble in water, but readily soluble in acids, ammonia, and ammonium salts; it separates from a hot solution of ammonium nitrate in microscopic needles. It turns yellow when treated with alkalis, and darkens on exposure to the air or on prolonged washing with water; it has an alkaline reaction, and explodes when heated. A yellow precipitate, which seems to have the composition $CH_2N_4O_2Ag_2$, is formed when soda or

barium hydroxide is added to a solution of nitroguanidine in ammoniacal silver nitrate; it is very hygroscopic, and decomposes very readily when dried at a moderate temperature. The *nitrate*, $CH_4N_4O_2,HNO_3$, crystallises from hot concentrated nitric acid in nacreous plates, and melts at 147°. The *hydrochloride*, $CH_4N_4O_2,HCl$, crystallises in plates or prisms. When nitroguanidine is treated with soda and zinc-dust, and then with a solution of a ferrous salt, a beautiful red coloration is produced; attempts to prepare alkyl and acidyl derivatives of nitroguanidine were unsuccessful.

Amidoguanidine hydrochloride, $NH_2{\cdot}NH{\cdot}C(NH){\cdot}NH_2,HCl$, can be obtained by gradually adding glacial acetic acid (124 grams) diluted with an equal volume of water, to a mixture of nitroguanidine (208 grams) and zinc-dust (700 grams) which has been previously rubbed to a thick paste with ice and water; during the addition of the acid, which occupies 2—3 minutes, the mixture is constantly stirred, and the temperature kept at 0° by adding ice. The temperature of the mixture is then allowed to rise slowly to 40—45°, and, as soon as a portion gives no coloration with soda and a ferrous salt, reduction is at an end; the filtered solution is then mixed with excess of hydrochloric acid, concentrated on the water-bath, taken up with alcohol, and evaporated to dryness; the residue consists of amidoguanidine hydrochloride, guanidine hydrochloride, and a little ammonium chloride, which are separated by means of alcohol. Amidoguanidine hydrochloride crystallises from dilute alcohol in large, thick prisms, melts at 163°, and is very readily soluble in water, but insoluble in ether; its physiological action is similar to that of guanidine and methylguanidine. The *platinochloride*, $(CH_6N_4)_2,H_2PtCl_6$, is a yellow substance melting at 145—146°. The *nitrate*, CH_6N_4,HNO_3, crystallises from water in large plates, from alcohol in needles, and melts at 144°; it is only sparingly soluble (12·01 parts in 100) in water at 15·9°. The *sulphate*, $(CH_6N_4)_2,H_2SO_4 + H_2O$, crystallises in needles, loses its water at 110°, and melts at 207—208° with decomposition; it is very readily soluble in water, but insoluble in alcohol. The *acid sulphate*, CH_6N_4,H_2SO_4, crystallises from water, in which it is only sparingly soluble, in small, yellow needles. When a solution of the sulphate is treated with the theoretical quantity of barium hydroxide, a solution of amidoguanidine is obtained; this solution gradually turns reddish on exposure to the air, and decomposes, with evolution of ammonia, when evaporated at a moderate temperature; on evaporation under reduced pressure, it yields a reddish, crystalline substance which has an alkaline reaction, and is soluble in alcohol, but insoluble in ether.

A compound of the composition $(CH_5N_4)_2Cu,2HNO_3$, is obtained as a violet, crystalline precipitate when a solution of amidoguanidine nitrate is treated with copper nitrate and sodium acetate; it crystallises in microscopic plates or prisms, and is only very sparingly soluble in cold water, yielding a violet solution; it is decomposed by boiling water with separation of copper, and also by ammonia and nitric acid. The corresponding *sulphate*, $(CH_5N_4)_2Cu,H_2SO_4$, prepared in like manner, is a violet, crystalline, sparingly soluble powder.

Acetylamidoguanidine nitrate, $C_3H_8N_4O,HNO_3 + H_2O$, is formed when amidoguanidine nitrate is heated with acetic acid and a few drops of nitric acid; it separates from water in large crystals which melt at 85—90°, and are readily soluble in water, but only sparingly in alcohol; these crystals lose their water at 55—60°, the anhydrous substance melting at 142—143° with decomposition. The *picrate*, $C_3H_8N_4O,C_6H_3N_3O_7$, crystallises from water in yellow needles.

When amidoguanidine is treated with dilute acids, or with caustic alkalis, it is first converted into semicarbazide with liberation of ammonia; the semicarbazide then undergoes decomposition into carbonic anhydride, ammonia, and hydrazine, identical with the compound described by Curtius.

Benzalsemicarbazide, $NH_2{\cdot}CO{\cdot}NH{\cdot}N{:}CHPh$, is obtained, together with benzalazine (compare Curtius and Jay, Abstr., 1891, 393), when an acid solution of the decomposition products of amidoguanidine is treated with benzaldehyde; it crystallises from water and alcohol in small, lustrous plates, melts at 214—220° with decomposition, and is moderately easily soluble in alcohol, but only sparingly in boiling water, and insoluble in cold ether.

Benzalamidoguanidine, $NH_2{\cdot}C(NH){\cdot}NH{\cdot}N{:}CHPh$, is precipitated in lustrous plates, when an aqueous solution of an amidoguanidine salt is treated with benzaldehyde and excess of concentrated potash; it melts at 178°, and is readily soluble in hot water and alcohol, but only sparingly in boiling benzene; its aqueous solution has an alkaline reaction, and gives precipitates with solutions of the heavy metals. The *hydrochloride*, $C_8H_{10}N_4,HCl + 3H_2O$, is deposited in colourless needles when hydrochloric acid is added to an aqueous solution of the base; it melts in its water of crystallisation when heated to about 50°, loses its water when kept under reduced pressure, and dissolves freely in water and alcohol; its aqueous solution gives, with mercuric chloride, a precipitate which is only sparingly soluble in cold water. The *aurochloride*, $C_8H_{10}N_4,HAuCl_4$, crystallises in slender, reddish-yellow needles, melts at 194°, and is only sparingly soluble in boiling water, by which it is decomposed. The *platinochloride*, $(C_8H_{10}N_4)_2,H_2PtCl_6 + 2H_2O$, crystallises in small needles, and melts at 208° when heated slowly. The *nitrate*, $C_8H_{10}N_4,HNO_3$, separates from boiling water in granular masses, melts at 158°, and is only sparingly soluble in cold water. The *nitrite*, $C_8H_{10}N_4,HNO_2$, crystallises from a mixture of chloroform and alcohol in colourless plates, melts at 137°, and turns brown on exposure to light; it is very readily soluble in water and alcohol.

Azodicarbonamidine nitrate, $NH_2{\cdot}C(NH){\cdot}N{:}N{\cdot}C(NH){\cdot}NH_2,2HNO_3$, is obtained as a yellow precipitate when a cold, saturated solution of potassium permanganate is gradually added to a solution of amidoguanidine nitrate in normal nitric acid. It is an intensely yellow, crystalline powder, explodes at 180—184° without melting, and is insoluble in alcohol and ether, and only very sparingly soluble in cold water; it dissolves in warm water and in alkalis, yielding intensely yellow solutions which undergo decomposition on boiling. With ammoniacal silver nitrate, it gives an orange-red, and with ammoniacal copper solutions, a brownish-black precipitate. The

picrate crystallises from warm water in orange-red plates, melts at 179—180° with decomposition, and is only sparingly soluble in hot water, by which it is decomposed.

Hydrazodicarbonamidine nitrate,

$$NH_2{\cdot}C(NH){\cdot}NH{\cdot}NH{\cdot}C(NH){\cdot}NH_2{,}2HNO_3 + H_2O,$$

is formed when the preceding compound is treated with the ordinary reducing agents, and is best prepared by passing hydrogen sulphide into water containing the nitrate in suspension; it separates from water in large, lustrous crystals, melts at 138° with sudden decomposition, and is sparingly soluble in alcohol; it loses its water under reduced pressure, and then melts at 132° with previous decomposition when quickly heated.

Azodicarbonamide, $NH_2{\cdot}CO{\cdot}N{:}N{\cdot}CO{\cdot}NH_2$, is obtained, together with ammonium nitrate and a very small quantity of a sparingly soluble, colourless compound, when hydrazodicarbonamidine nitrate is boiled with water for 10—15 minutes; it is an orange-red, crystalline powder, very sparingly soluble in hot water, and insoluble in alcohol and cold water. When heated at 180—200°, it turns white, with evolution of ammonia, and the residue consists principally of cyanuric acid; when treated with phenol and concentrated sulphuric acid successively, there is produced a dark-green coloration which becomes yellow on diluting, and green again on adding alkali.

Hydrazodicarbonamide, $NH_2{\cdot}CO{\cdot}NH{\cdot}NH{\cdot}CO{\cdot}NH_2$, is formed when the azo-compound is reduced with hydrogen sulphide in boiling aqueous solution, or boiled with concentrated hydrochloric acid; it can also be prepared by treating hydrazine sulphate with potassium cyanate in aqueous solution. It crystallises from water in colourless, microscopic plates, melts at 244—245° with decomposition, and is insoluble in alcohol and ether, and only very sparingly soluble in boiling water; it reduces ammoniacal silver solutions.

Diazoguanidine nitrate, $NH_2{\cdot}C(NH){\cdot}NH{\cdot}N{:}N{\cdot}NO_3$, is best prepared by adding sodium nitrite to a nitric acid solution of amidoguanidine nitrate, the temperature being kept below 40°; it crystallises from boiling alcohol in plates or prisms, melts at 129°, and is readily soluble in water and alcohol, but insoluble in ether. Its aqueous solution is stable at the ordinary temperature, as is also the dry diazo-compound; on treatment with hydrogen sulphide, it is converted into guanidine. The *hydrochloride* forms large plates. The *picrate*, $CH_4N_5{,}C_6H_3N_3O_7$, crystallises in small, yellow needles, and is very sparingly soluble in water.

When amidoguanidine nitrate is treated with sodium nitrite in acetic acid solution, there is precipitated a yellow, amorphous, explosive substance which has the composition $C_2H_8N_{10}O$.

When a solution of diazoguanidine nitrate is treated with an ammoniacal solution of silver nitrate, a yellow precipitate is produced, and, on acidifying the filtrate with dilute nitric acid, a small quantity of silver nitride is thrown down; the yellow precipitate has the composition CN_5Ag_3, and is probably a molecular compound of silver cyanamide and silver nitride; when treated with dilute nitric acid, silver nitride remains undissolved, and silver nitrate and cyanamide

pass into solution. When an ammoniacal solution of copper sulphate is added to a solution of a diazoguanidine salt, a dark-brown precipitate of copper cyanamide, mixed with a little copper amidotetrazotate, is produced, and the filtrate contains a large quantity of hydrogen nitride.

Diazoguanidine salts are decomposed by alkalis, yielding cyanamide and hydrogen nitride; this reaction can be conveniently employed for the preparation of the last-named compound.

Amidotetrazotic acid, $\begin{matrix}N—N\\ \|\\ N\cdot NH\end{matrix}\!\!>\!C\cdot NH_2$, is formed, together with hydrogen nitride, when diazoguanidine salts are boiled with dilute acids; when acetates or carbonates are employed, instead of dilute acids, amidotetrazotic acid is the sole product. It crystallises from water in lustrous plates or prisms which contain 1 mol. H_2O, and melt at 203° (corr.); it is soluble in 82·25 parts of water at 18·4°, and dissolves freely in hot water, but is only sparingly soluble in alcohol, and insoluble in ether. It seems to be completely decomposed by potassium permanganate in alkaline solution; aqueous solutions of the acid give precipitates with solutions of cupric, mercuric, and mercurous salts. The *sodium* salt, $CH_2N_5Na + 3H_2O$, prepared by treating the acid with sodium carbonate, crystallises in large prisms, is readily soluble in water, and is decomposed by acetic acid. The *barium* salt, $(CH_2N_5)_2Ba$, separates from hot dilute alcohol in needles which seem to contain 5 mols. H_2O. The *silver* salt, CH_2N_5Ag, is stable in the light, but explodes when heated; it is only very sparingly soluble in warm nitric acid. The *hydrochloride*, $CH_3N_5,HCl + H_2O$, is deposited in prisms when the acid is dissolved in warm, concentrated hydrochloric acid, and the solution allowed to cool; it loses its water under reduced pressure, and is reconverted into amidotetrazotic acid when heated at 95—100°, or when treated with water.

When sodium amidotetrazotate is treated with sodium nitrite and dilute hydrochloric acid in the cold, diazotetrazole is formed; this compound cannot be isolated on account of its instability. Moderately concentrated solutions explode even at 0° after a few seconds, and more dilute solutions gradually decompose on keeping.

Tetrazoleazodimethylaniline, $CN_4H\cdot N{:}N\cdot C_6H_4\cdot NMe_2$, is precipitated when dilute solutions of dimethylaniline and sodium acetate are added to a dilute solution of diazotetrazole; it crystallises from alcohol in red plates, begins to decompose at 150°, explodes at about 155°, and is only sparingly soluble in water and ether. The *hydrochloride* is a brownish-green compound, and is decomposed by water. The *sodium* derivative crystallises from water in small, red, lustrous octahedra, and from soda, in which it is more sparingly soluble, in needles, very similar in appearance to the crystals of chromic acid.

Tetrazoleazo-β-naphthylamine, $CN_4H\cdot N{:}N\cdot C_{10}H_6\cdot NH_2$, prepared in like manner, separates from alcohol in the form of a lustrous, green powder, melts at about 184°, and is readily soluble in soda, but only sparingly in alcohol, and almost insoluble in water.

F. S. K.

Supposed Reaction of Spermine. By Duclaux (*Compt. rend.*, **115**, 155—157).—The increased rate of decomposition of water by magnesium and gold chloride attributed by Poehl to the chemical action of spermine is due to physical action, the spermine causing a froth, and thus exposing a large surface to the action of the magnesium-gold couple. Other substances of a similar nature, such as soapy water, saponin, panamin, and egg-albumin, have the same effect. The same amount of hydrogen and magnesia, moreover, are ultimately formed in the absence of froth-producing material. Jn. W.

Action of Zinc and Ethyl Monochloracetate on the Aldehydes. By S. Reformatsky (*J. Russ. Chem. Soc.*, **22**, 194—208).—The analogy between the ketones and aldehydes renders it probable that the latter by the action of zinc and ethyl monochloracetate should yield β-hydroxy-acids. Experiments made in this direction have, however, not confirmed the supposition. On heating ethaldehyde with zinc and ethyl monochloracetate, a very small amount of hydroxy-acid seems to be formed; this, however, the author attributes to secondary reactions. Experiments with propaldehyde did not yield hydroxyvaleric acid, but a mixture of propionic acid with glycollic acid, and a neutral product. Analysis of the latter gave numbers which corresponded most closely with the formula $C_{10}H_{20}O_3$, but the author thinks the true formula must be $(C_3H_6O)_3$. As this compound is entirely different in its properties from aldol, the author comes to the conclusion that it must be a polymeride of propaldehyde, and probably an analogue of paraldehyde. The conclusion that it contains no aldehyde groups was confirmed by the negative results obtained on treating it with rosaniline and hydroxylamine. On distilling it with a drop of sulphuric acid, it was changed into propaldehyde, just as paraldehyde is into ethaldehyde. Vapour density determinations by V. Meyer's method in toluidine vapour gave the numbers 6·36, 6·63; in naphthalene vapour, 5·95; the theoretical number is 6·02.

The author calls the compound parapropaldehyde; it is a mobile liquid boiling at 169—170° (768 mm.), insoluble in water, easily soluble in alcohol and ether. It could not be solidified in a freezing mixture of snow and concentrated hydrochloric acid.

The author thinks that a compound $COOEt{\cdot}CH_2{\cdot}ZnCl$ is formed as an intermediate product in the reaction. The action of zinc chloride alone does not yield parapropaldehyde.

The action of zinc and ethyl monochloracetate on isobutaldehyde yielded no hydroxy-acid; isobutyric and formic acids were formed, and the sodium salts crystallised out together in the proportion of 3 to 1 from an alcoholic solution; besides these, a neutral compound which gave a violet colour with rosaniline was also produced, but was not further investigated.

The action of zinc and ethyl monochloracetate on œnanthol yielded œnanthylic acid and a dark-coloured neutral product, which was not investigated.

Benzaldehyde similarly treated yielded benzoic acid. M. F.

Action of Iodine on the Silver Salts of Fatty Acids. By A. Simonini (*Monatsh.*, **13**, 320—325).—The author has repeated the experiments of Birnbaum (*Annalen*, **152**, 111), who states that he obtained silver iodide, carbonic anhydride, acetic acid, methyl acetate, hydrogen, and acetylene by the action of iodine on silver acetate, and finds that, when heated together at 130—140°, the substances yield only the four products first named. Neither hydrogen nor any unsaturated hydrocarbon is formed, and the yield of methyl acetate is about 50 per cent. of that required by the equation $2CH_3{\cdot}COOAg + I_2 = 2AgI + CO_2 + CH_3{\cdot}COOMe$.

Iodine and silver caproate, when heated together at about 100°, behave in a precisely similar way, forming silver iodide, carbonic anhydride, and normal amyl caproate, the yield of the last-named being about 75 per cent. of that corresponding with the equation $2AgC_6H_{11}O_2 + I_2 = C_5H_{11}{\cdot}C_6H_{11}O_2 + CO_2 + 2AgI$. G. T. M.

An Additive Compound of Hydrogen Cyanide with Ethyl α-Cyanopropionate. By N. Zelinsky and A. Buitchichin (*J. Russ. Chem. Soc.*, **22**, 169—171).—It has been previously observed (Abstr., 1889, 377) that when potassium cyanide acts on ethyl α-bromopropionate, besides the two compounds ordinarily obtained (ethyl α-cyanopropionate and a condensed product, the ethyl salt of symmetrical dimethylcyanosuccinic acid), a third crystalline nitrogenous substance is formed. The supposition then made, that this product is an additive product of hydrogen cyanide with ethyl α-cyanopropionate, has been confirmed by analysis as well as synthetically.

By the action of a strong solution of sodium or potassium hydroxide, it is easily dissolved in the cold with considerable development of heat, and if this solution is acidified with hydrochloric acid and distilled in a current of steam, a considerable quantity of hydrocyanic acid passes over. If, however, water is added to the potash solution and the mixture is heated, ammonia is given off. On heating the solution until ammonia ceases to be evolved, acidifying with hydrochloric acid, extracting with ether, and evaporating the ethereal solution, a crystalline, organic acid is left which melts at 130°, the melting point of isosuccinic acid. Its silver salt, dried at 115° to 120°, was analysed, and gave results corresponding with the formula $C_4H_4O_4Ag_2$. The analysis of the additive compound corresponds with the formula $C_7H_{10}N_2O_2$.

It has also been obtained by the action of an aqueous solution of potassium cyanide, to which some hydrochloric acid is added, on an alcoholic solution of ethyl α-cyanopropionate.

From these facts the author concludes that the formula of the compound is $CN{\cdot}NH{:}C{\cdot}CHMe{\cdot}COOEt$. It is insoluble in cold water, and sublimes readily in a current of steam. It is easily soluble in ether and hot alcohol, slightly so in benzene and cold alcohol. The crystals belong to the rhombic system, and show a combination of the prism, brachypinacoid, and macropinacoid. A determination of the molecular weight in benzene by Raoult's method gave the theoretical number 154. M. F.

Dimethylamidopropionic Acid. By E. Duvillier (*Bull. Soc. Chim.* [3], **7**, 99—102).—*Dimethylamidopropionic acid*,

$$CH_3{\cdot}CH(NMe_2){\cdot}COOH,$$

is obtained by heating excess of an aqueous solution of dimethylamine (3 mols.) with α-bromopropionic acid (1 mol.) for several hours in a sealed tube at 100°. The product is treated with boiling barium hydrate solution, the barium carefully precipitated with sulphuric acid, and silver oxide added. The silver is removed by hydrogen sulphide and the solution warmed for 8—10 hours with freshly precipitated copper hydroxide; the copper salt thus formed is then decomposed by hydrogen sulphide, and the acid precipitated as a pasty mass by adding ether to its alcoholic solution. The syrupy aqueous solution after a time deposits the acid as slender needles; on heating, it melts and volatilises with partial decomposition. It is very soluble in water and alcohol, insoluble in ether. The *hydrochloride* crystallises in tufts of needles, and is very soluble in alcohol and water. The *platinochloride* crystallises in the monosymmetric system with 4 mols. H_2O, which are lost at 110°; it is soluble in alcohol and water, insoluble in dry ether. The *aurochloride* is obtained in monosymmetric crystals, very soluble in water, alcohol, and ether-alcohol, sparingly soluble in ether. The *stannochloride* is a deliquescent, crystalline salt, soluble in water and alcohol. The *cadmium* salt resembles the *zinc* salt, which is obtained from its aqueous solution as a syrup, but ultimately solidifies; they are both soluble in alcohol. The *copper* salt forms beautiful blue, monosymmetric crystals containing 7 mols. H_2O; the last molecule of water is only lost on prolonged heating at 120°. Aqueous solutions of the salt undergo partial reduction at 120° with deposition of metallic copper. W. J. P.

Action of Ammonia on Bromisobutyric Acid. By E. Duvillier and F. Chancel (*Bull. Soc. Chim.* [3], **7**, 102—104; compare *Bull. Soc. Chim.* [3], **5**, 848).—A mixture of bromisobutyric acid (1 mol.) and aqueous ammonia (3 mols.) was heated in a closed tube at 100° for several hours. The product was then treated with excess of barium hydroxide, the ammonia boiled off, and the barium eliminated by adding exactly the necessary quantity of sulphuric acid. On distilling the aqueous solution, a distillate was obtained from which a mixture of isobutyric acid and about 8 per cent. of a crotonic acid, probably methacrylic acid, was separated. The residual liquid from the distillation yielded hydroxyisobutyric acid on extraction with ether. By further treating the solution with silver oxide, eliminating the silver by hydrogen sulphide, evaporating to dryness, extracting with alcohol, and precipitating the alcoholic solution with ether, amidoisobutyric acid was obtained. W. J. P.

Monobromocerotic Acid. By T. Marie (*Bull. Soc. Chim.* [3], **7**, 111—113).—A *bromo*-derivative of cerotic acid, $C_{25}H_{51}{\cdot}CHBr{\cdot}COBr$, is prepared by allowing dry bromine (2·5 c.c.) to act drop by drop on an intimate mixture of cerotic acid (10 grams) and amorphous phosphorus (0·3 gram) and heating on the water-bath for six hours. The

product is poured into water and the pasty mass extracted with petroleum after washing. On repeated crystallisation from petroleum, the brominated derivative is obtained in stellate groups of needles melting at 65—66°. W. J. P.

Reciprocal Transformation of Lactones and Hydroxy-acids. By P. Henry (*Zeit. physikal. Chem.*, **10**, 96—129).—Lactones, being the internal ethereal salts of hydroxy-acids, may be hydrolysed by means of bases just like other ethereal salts; and the change in aqueous solution might be expected to obey the same laws in both cases. The author has studied the rate of hydrolysis of butyrolactone and of valerolactone by different bases in dilute solution (1/200-normal) at 25°, and finds the following velocity constants:—

Base.	Butyrolactone.	Valerolactone.	Ratio.
KOH	0·253	0·131	1·93
NaOH	0·255	0·127	2·00
$Ca(OH)_2$	0·241	0·124	1·94
$Sr(OH)_2$	0·250	0·126	1·99
$Ba(OH)_2$	0·248	0·125	1·97
NH_2Me	0·0530	0·0230	2·31
NH_2Et	0·0532	0·0268	1·98
$NHMe_2$	0·0576	0·0326	1·77
NH_3	0·02	0·01	2·00

A comparison of the numbers obtained in this way for butyrolactone with those got by Ostwald for the hydrolysis of ethyl acetate in 1/40-normal solution results as follows:—

Base.	Butyrolactone, 1/200-normal.	Ethyl acetate. 1/40-normal.
KOH	253·0	253·0
NaOH	255·0	254·0
NH_2Me	53·3	29·9
NH_2Et	53·2	29·9
$NHMe_2$	57·6	35·4
NH_3	20·0	4·7

The values for potash have been made equal in the two cases. It will be observed that the increased dilution in the case of the feebler bases greatly increases the relative velocity coefficient, owing to the increased dissociation. Calculation shows that it is the hydroxyl ion of the base that actually effects the hydrolysis.

The author also investigated the transformation of γ-hydroxybutyric and γ-hydroxyvaleric acids into their respective lactones in aqueous solution under the influence of acids. The catalytic action of the added acids is proportional to their coefficients of affinity, Hydroxyvaleric acid is more easily transformed into the lactone than hydroxybutyric acid; this corresponds with the greater stability of valerolactone as compared with butyrolactone.

The γ-hydroxy-acids do not need the addition of a foreign acid to

convert them into lactones. On standing in aqueous solution, they undergo the transformation spontaneously. This is a case of what Ostwald has called "autocatalysis," the hydrogen ions split off from the acid itself being the agents that effect the decomposition of the undissociated portion of the acid. J. W.

Stereochemistry of Trihydroxystearic Acids prepared from Ricinoleïc Acid and from Ricinelaïdic Acid. By K. Mangold (*Monatsh.*, **13**, 326—329).—A mixture of two hydroxystearic acids is formed by the oxidation of ricinoleïc acid, which, according to the investigations of Krafft, has the constitution

$$CH_3\cdot[CH_2]_5\cdot CH(OH)\cdot CH{:}CH\cdot[CH_2]_8\cdot COOH,$$

since secondary capryl alcohol and sebacic acid may be obtained from it. To account for this fact, Hazura and Grüssner (Abstr., 1888, 1270) have made the suggestion that ricinoleïc acid is not a single substance but a mixture of two acids. The author, however, points out that such a supposition is unnecessary, as a more satisfactory explanation is, that a single acid gives rise to two stereoisomeric oxidation products.

Hazura and Grüssner (Abstr., 1889, 956) obtained only one product of oxidation of ricinelaïdic acid, but the author finds that, on oxidation with alkaline potassium permanganate, two distinct acids are formed. These are well characterised; one crystallises from alcohol in microscopic prisms and from ether in microscopic rhombohedra, and melts at 117—120°; the other crystallises in slender needles and melts at 113—116°. G. T. M.

Constitution of Tiglic and Angelic Acids. By I. Kondakoff (*J. Russ. Chem. Soc.*, **22**, 375—380).—The author adduces the following observations made by him in support of the formulæ $CH_2{:}CH\cdot CHMe\cdot COOH$ and $CH_3\cdot CH{:}CMe\cdot COOH$ for angelic and tiglic acids respectively. Tiglic acid, when oxidised with potassium permanganate, yields, as products of oxidation, acetaldehyde, acetic acid, dihydroxytiglic acid, along with other neutral and acid compounds of undetermined constitution. Neither propionic nor oxalic acid is formed. The chief product is acetaldehyde. Angelic acid, on being similarly treated, yields acetaldehyde and small quantities of another aldehyde, the acid corresponding with which forms a very sparingly soluble, crystalline silver salt. Oxalic acid is formed, and another acid, which is not crystalline, is excessively hygroscopic, and whose salts are amorphous and soluble in water, but insoluble in alcohol. The calcium salt, dried at 117°, contains 16·3 per cent. of calcium.

The author also investigated the additive products obtained by the action of fuming hydriodic acid on angelic acid and its ethyl salt, and the substances produced from them by the action of moist silver oxide. J. W.

Action of Methylene Iodide on Diethyl Malonate. By S. Tanatar (*J. Russ. Chem. Soc.*, **22**, 314—317); compare Abstr., 1891, 174 and 175.—The yellow oil obtained on distilling the acid

$OEt{\cdot}CH_2{\cdot}CH(COOH)_2$ was saponified. The acid thus produced is a thick liquid which may be extracted from its aqueous solution by agitation with ether. The soluble calcium salt is precipitated by silver nitrate with formation of the salt $C_6H_8Ag_2O_5$, which blackens in the light, but remains undecomposed up to 100°; above this temperature it decomposes quietly. A strong aqueous solution of the acid heated at 160° with hydriodic acid yields yellow, shining plates (*β*-iodopropionic acid ?) on cooling.

The ethereal salt produced by the action of methylene iodide on ethyl malonate has the molecular weight 363, according to observations on the freezing point of its acetic acid solutions. The molecular weight of diethyl methylenemalonate is 172. On hydrolysis, it yields calcium salts of the formulæ $C_8H_6Ca_2O_9$ and $C_4H_4CaO_5$, and silver salts $C_8H_6Ag_4O_9$ and $C_4H_4Ag_2O_5$. These correspond with two gummy acids $C_4H_6O_5$ and $(C_4H_6O_5)_2 - H_2O$.

When the saponification of the oil is conducted in absence of water, another acid is formed. The potassium salt of this acid separates from its alcoholic potash solution as a viscous mass, which readily dissolves in water. The acid is soluble in water and in ether, and remains as a honey-like mass on evaporating its solutions. The lime salt has the composition and properties of calcium ethoxyisosuccinic acid. The acid heated in a sealed tube with hydriodic acid yields ethyl iodide. Its formation may be represented by the equation $CH_2{:}C(COOH)_2 + EtOH = OEt{\cdot}CH_2{\cdot}CH(COOH)_2$. J. W.

Action of Alcoholic Potash on Bromisosuccinic Acid. By S. Tanatar (*J. Russ. Chem. Soc.*, **22**, 313—314).—If the acid $C_6H_{10}O_5$, obtained by the action of alcoholic potash on bromisosuccinic acid (Abstr., 1890, 1238), is heated with aqueous hydriodic acid, an acid melting at 140° is obtained. This acid crystallises in plates from ether, and from water in needles; its calcium salt is sparingly soluble in water. The author regards it as isomalic acid.

The acid $C_6H_{10}O_5$ would thus be ethoxyisosuccinic acid,

$$COOH{\cdot}CMe(OEt){\cdot}COOH,$$

different from the isomeric acid, $COOH{\cdot}CH(CH_2{\cdot}OEt){\cdot}COOH$, obtained from diethyl malonate by the action of methylene iodide (compare preceding abstract). No analyses are given. J. W.

Transformation of Maleïc into Fumaric Acid. By S. Tanatar (*J. Russ. Chem. Soc.*, **22**, 310—312).—If an aqueous solution of maleïc acid (10 to 30 per cent.) is heated for two hours at 200° in a sealed tube, practically the whole of the maleïc is converted into fumaric acid. Small quantities of maleïc acid remain unchanged, and sometimes traces of a very soluble acid are found in the solution. At 160° no change takes place. If Wislicenus' explanation of the action of the halides of hydrogen in converting maleïc into fumaric acid is applied to this case, malic acid ought to be formed as an intermediate product, and should, therefore, by heating with water at 200°, be converted into fumaric acid. The author finds that this is not the case, and that the acid formed by the prolonged heating of

fumaric acid with water (*Ber.*, **14**, 2648) reproduces no fumaric acid on heating with water at 220°. Maleïc acid, heated by itself in a closed tube at 200°, is completely transformed in the course of 1—2 hours into fumaric acid.

These facts the author considers to be at variance with Wislicenus' hypothesis, and he is inclined to the assumption that atoms and atomic groups can not only move from one carbon atom to another within a molecule, but also from one corner to another of the same carbon tetrahedron. J. W.

Complete Transformation of Fumaric into Maleïc Acid. By S. Tanatar (*J. Russ. Chem. Soc.*, **22**, 312—313).—If a mixture of equal volumes of fumaric acid and phosphoric anhydride is heated in a retort, a colourless liquid distils at 160° into the receiver, where it solidifies on cooling. This is maleïc anhydride, which may be obtained perfectly pure by recrystallisation from chloroform. On heating the anhydride with water at 50—60°, the acid is formed, and dissolves.

Fumaric acid may be distilled without decomposition under a pressure of 50—70 mm. J. W.

Tetramethylenedicarboxylic Acids. By V. Markovnikoff (*J. Russ. Chem. Soc.*, **22**, 279—290).—Markovnikoff and Krestovnikoff prepared an acid of the composition $C_6H_8O_4$ by the action of dry sodium ethoxide on ethyl α-chloropropionate. They found that this acid did not behave as an unsaturated acid, and they gave to it the name *symmetrical tetrylenedicarboxylic acid* and the formula

$$\begin{array}{l} CH_2{\cdot}CH{\cdot}COOH \\ | \quad\quad | \\ COOH{\cdot}CH{-}CH_2 \end{array}$$

(*J. Russ. Chem. Soc.*, **11**, 455, and **12**, 460).

It crystallises from water in four-sided prisms, is easily soluble in cold absolute alcohol, but much less so in ether. 100 parts of water at 17—20° dissolve 3·8 parts of the acid. Heated for 48 hours with water containing a few drops of sulphuric acid, it remained unchanged. With hydriodic acid (sp. gr. 1·96), it showed signs of decomposition at 180°, but even after prolonged heating at 250° there was only a slight pressure of gas in the tube. No carbonic anhydride was formed, the gas evolved being combustible (C_4H_8?). The acid chloride was prepared from the sodium salt and phosphorus pentachloride at the ordinary temperature. It crystallises from ether in needles. The amide may be prepared by treating the ethereal solution of the acid chloride with strong aqueous ammonia. Silver nitrate gives no precipitate with a solution of the sodium salt at first, but after some time a crystalline powder falls out; a considerable quantity, however, remaining dissolved.

When the acid was treated with twice its weight of acetic chloride, it did not dissolve at the ordinary temperature, but did so at 90°. The solution kept over solid sodium hydroxide for a week in a vacuum left a mass of crystals melting at 166—169°; these contained chlorine

and gave off acetic chloride on heating, and are probably the acetochloranhydride, $COCl{\cdot}C_4H_6{\cdot}COOAc$. The crystals are fairly soluble in ether. The same compound is obtained, along with the mixed anhydride, by the action of acetic chloride on the silver salt. If the anhydride alone is wanted, a slight excess of the silver salt is taken, covered with a considerable quantity of ether, and acetic chloride dissolved in ether is allowed to drop slowly in. After five hours' heating with a reflux condenser, the liquid no longer contains chlorine; it is then filtered from the silver chloride, the ether distilled off, and the residue placed in a vacuum over sulphuric acid. It forms a viscous liquid heavier than water, in which it dissolves slowly in the cold, but more quickly on heating, losing at the same time its aromatic odour. The aqueous solution, on cooling, deposits the original acid, and contains acetic acid. Ethyl acetate is formed when the substance is dissolved in alcohol. A titration with soda of the aqueous solution of a weighed portion corresponded with the formula $C_4H_6(COOAc)_2$.

Heated at 150—160° in a test-tube, the mixed anhydride gives off acetic acid vapours, and tetrylenedicarboxylic acid remains. When the mixed anhydride is heated strongly in a retort, acetic anhydride distils over, the thermometer indicating a temperature of 180°. Suddenly it rises to 240°, a new substance then distilling. The distillation is stopped when the product begins to become brown. On redistillation, the higher boiling product comes over at 250—252°, solidifying in the receiver. It is the anhydride of an acid isomeric with the symmetrical dicarboxylic acid. Its melting point is 49—50°, and its boiling point 254—255° (corr.). It is moderately soluble in water, forming an acid, 33·7 parts of which dissolve at 21° in 100 parts of water. The acid crystallises in rhombs or short prisms, melts at 138—139° (uncorr.), and is very soluble in alcohol, but only very slightly in ether. It remains unchanged on being heated at 200° with weak hydrochloric acid, but a slight odour of formic acid is observable when it is heated at 250° with dilute sulphuric acid. On being heated by itself, it loses water and forms the anhydride. The sodium salt crystallises in short needles from very strong solutions. The ammonium salt is also very soluble, and crystallises in slender needles. The calcium salt is not formed by precipitation, except on heating. The barium salt, $BaC_6H_6O_4 + 2H_2O$, is precipitated when barium chloride is added to the solution of the sodium salt. Magnesium, zinc, and mercury salts are not formed by precipitation. Those of lead and copper come down in hot solution, but the precipitates dissolve again on cooling. The silver salt is a heavy, crystalline powder, very sparingly soluble in water.

The anhydride of the lower melting acid may be prepared directly from the symmetrical acid; the latter is not changed at a temperature of 300°, but on being heated rapidly with a burner, unchanged acid and the anhydride of the isomeric acid are driven over. Careful heating drives over water first, and then anhydride, which condenses in oily drops in the receiver. This oil, on being redistilled, gives the pure anhydride. The aqueous layer contains some of the corresponding acid.

Although there are many analogies between the behaviour of the

two tetrylenedicarboxylic acids and the two symmetrical diethylsuccinic acids, the author does not consider the isomerism to be of the same type in the two cases. The acid of melting point 170° he regards as paratetramethylenedicarboxylic acid, and the acid of melting point 138° as orthotetramethylenedicarboxylic acid. The latter should then be identical with Perkin's acid (m. p. 130°) from $\begin{matrix}CH_2\cdot C(COOH)_2\\ |\\ CH_2\cdot C(COOH)_2\end{matrix}$. Perkin's anhydride, however, melts at 76—78° instead of 49—50°. J. W.

Specific Rotatory Power of Tartaric Acid and its Salts. By A. A. KANONNIKOFF (*J. Russ. Chem. Soc.*, **22**, 369—375).—The author has shown how to calculate the specific rotatory power of a dissolved substance from observations of the minimum refraction and rotation of the plane of polarisation of two solutions of the substance having different (unknown) concentrations. The nature of the solvent has no influence on the constant, provided that it does not affect the dissolved substances chemically. For tartaric acid, the specific rotatory power, $[\alpha]_D$, is +12·46°; for its acid salts (of sodium, lithium, potassium, ammonium), +24·48° on the average; and for its normal (simple or double salts) of the same metals, +30·44° as a mean. The salts of various organic radicles were examined in aqueous and in alcoholic solution, and in many cases the values found for them were such as to indicate a decomposition of the salt by the solvent. The following table gives the results obtained with solutions having the acid and base in proportions corresponding with the normal salts:—

Base in salt.	$[\alpha]_D$ for aqueous solution.	$[\alpha]_D$ for alcoholic solution.
Ethylamine	24·63°	30·62°
Propylamine	24·65	30·70
Isobutylamine ...	18·16	30·63
Isoamylamine ...	12·19	24·26
Diisobutylamine .	12·69	24·36
Diamylamine	12·22	18·37
Triethylamine ...	12·46	18·86
Aniline	12·62	
Orthotoluidine...	12·89	
Paratoluidine....	12·44	
Quinoline	12·36	

A comparison of these numbers with those obtained for the metallic salts shows that water decomposes to a greater or less extent the normal salts of all the bases examined. Thus the normal salts of ethylamine and propylamine are decomposed apparently into the acid salts and free base; in the case of isobutylamine, the decomposition proceeds further; and for the other bases it seems to be complete, the values obtained being practically identical with that of the free acid. Alcohol is much less active as a decomposing agent, the salts

of ethylamine, propylamine, and isobutylamine being unaffected, whilst those of the remaining bases are only partially decomposed.

J. W.

The Volatility of Carbamide and its Crystallisation by Sublimation in a Vacuum. By L. Bourgeois (*Bull. Soc. Chim.* [3], **7**, 45—47).—Wiedemann, when preparing biuret, first noticed that carbamide would volatilise without decomposition. In an open tube, sublimation occurs to a slight extent at 120—130°. If, however, the carbamide is introduced into a tube, a small plug of cotton wool placed above it, and, after exhaustion, the tube is heated in a mercury bath at 120—130° for 15 minutes, sublimation occurs rapidly, long prisms of carbamide are found entangled in the wool, and, above the plug, transparent, tetragonal and octagonal tables. Thiourea, when heated in a vacuum at 150—160°, sublimes as ammonium thiocyanate.

T. G. N.

Thiourea. By G. Carrara (*Gazzetta*, **22**, i, 343—347).—Hintze (*Jahresber. der Chem.*, 1884, 462) observed that in the preparation of thiourea from ammonium thiocyanate by Reynolds' method, the mother liquors (especially in presence of an excess of thiocyanate) form a deposit of silky needles; these consist of a compound of thiourea and ammonium thiocyanate in molecular proportion. The compound is best prepared by dissolving equal weights of thiourea and ammonium thiocyanate in water and allowing the solution to evaporate. The crystals melt at 144°, have a sp. gr. of 1·4307; 23·1 parts dissolve in 100 parts of water at 25°. They dissociate in aqueous solution.

The author has determined the following constants for thiourea, namely:—melting point, 169°; sp. gr. = 1·4009; solubility, 13·76 parts in 100 of water at 24°; density of aqueous solution saturated at 24° = 1·038.

S. B. A. A.

Action of Aluminium Chloride on Aromatic Hydrocarbons. By R. Heise and A. Töhl (*Annalen*, **270**, 155—171; compare Heise, Abstr., 1891, 685).—The authors have studied the behaviour of various aromatic hydrocarbons with aluminium chloride and hydrogen chloride at 100°. In the first place they confirm the conclusions arrived at by Anschütz and Immendorff (*Annalen*, **235**, 189), and find that ethylbenzene yields benzene, paradiethylbenzene, a small quantity of metadiethylbenzene, and triethylbenzene.

When isopropylbenzene is treated with aluminium chloride and hydrogen chloride at 100°, it yields propane, benzene, and meta- and para-diisopropylbenzene; the same two diisopropylbenzenes are obtained as bye-products in the preparation of isopropylbenzene by Friedel and Craft's method, so that the compounds described by Uhlhorn (Abstr., 1891, 184) as derivatives of orthodiisopropylbenzene are, in reality, the corresponding para-compounds.

Butylbenzene, treated with aluminium chloride under the conditions already mentioned, yields benzene, and meta- and para-dibutylbenzene. Orthoxylene gives, principally, metaxylene, together with small quantities of benzene, paraxylene, pseudocumene, and mesi-

tylene; paraxylene is also converted for the most part into metaxylene, the other products being the same as in the case of orthoxylene. Metaxylene yields a small quantity of benzene, paraxylene, and trimethylbenzene, but the greater portion remains unchanged. F. S. K.

Synthesis of Cymene. By L. Reuter (*Chem. Centr.*, 1892, i, 625; from *Apoth. Zeit.*, **7**, 137; compare this vol., p. 623).—By the employment of 40—50 grams of isopropyl iodide and the corresponding quantity of parabromotoluene only traces of cymene are obtained, the chief products being diisopropyl, ditolyl, stilbene, &c. If 10—15 grams of isopropyl iodide, however, are used, 3 grams of cymene (paramethylisopropylbenzene), boiling at 174—176°, can be isolated. The action is not so violent in the latter case, and the results generally are better than Brühl represents (this vol., p. 623). A. G. B.

Displacement of Hydrogen by Haloïds in Aromatic Hydrocarbons. By Miss P. Lazareff (*J. Russ. Chem. Soc.*, **22**, 385—388).—The chlorides and bromides of sodium, potassium, barium, zinc, and cadmium are all active in facilitating the introduction of bromine into the benzene molecule. 5 grams of iodine, sealed up with 50 grams of benzene and 10 of mercuric chloride, gave a colourless liquid at the end of a week in the dark. Part of the mercuric chloride was transformed into the iodide, and hydrogen chloride was evolved on the tube being opened. The authoress inclines to the opinion that the activity of salts as halogen-carriers depends in the first place on their solubility in the liquid employed. Thus mercuric chloride and bromide in the above case are more active than the corresponding salts of the alkali metals, and are also more soluble in benzene. J. W

Iodobenzenes. By Istrati and Georgescu (*Chem. Centr.*, 1892, i, 625; from *Bull. Soc. Sci. Fiz. Bucuresci*, **1**, 56; compare Abstr., 1891, 1197).—The following iodobenzenes, the last four of which have not been described heretofore (compare *Watts' Dict.*, 2nd Ed., iii), were obtained by heating benzene with iodine and strong sulphuric acid in a reflux apparatus: C_6H_5I (b. p. 185·5—186·5°); $C_6H_4I_2$ [1 : 4] (m. p. 129°; b. p. 280—282°); $C_6H_4I_2$ [1 : 2] (m. p. 7—8°; b. p. 280—282°); $C_6H_3I_3$ [1 : 2 : 4 (?)] (m. p. 85°); $C_6H_3I_3$ [1 : 2 : 3 (?)] (m. p. 182—184°); $C_6H_2I_4$ [1 : 2 : 4 : 5 (?)] (m. p. 236°); $C_6H_2I_4$ (m. p. 220°). A. G. B.

Naphthenes and Polymethylenes. By V. Markovnikoff (*J. Russ. Chem. Soc.*, **22**, 275—279).—In this paper the author discusses the question of the identity of the naphthenes from Caucasus petroleum and the polymethylenes. The naphthenes proper he considers to be identical with hexamethylene (hexahydrobenzene) and its homologues. Thus, hexanaphthene is hexahydrobenzene, octonaphthene is hexahydrometaxylene, isooctonaphthene the corresponding para-compound, and nononaphthene probably hexahydropseudocumene. The naphthenes in general may also include derivatives of other polymethylene rings. Attention is drawn to the

practical identity of the boiling points of the polymethylene derivatives, and of the corresponding paraffins. J. W.

Naphthenes and their Derivatives in the General System of Organic Compounds. By V. Markovnikoff (*J. pr. Chem.* [2], **46**, 86—106).—The conclusion of the author's review of the subject (this vol., p. 1182). A. G. B.

Action of Non-metallic Nitrides and Hydronitrides on Hydroxycarbon Compounds. By R. Vidal (*Compt. rend.*, **115**, 123—124).—When phospham is heated with phenol in sealed tubes at 300°, diphenylamine is the only product, and 90 per cent. of the calculated yield is obtained.

Boron nitride, when heated with methyl alcohol in a closed vessel at about 250°, yields a distinctly crystallised borate of dimethylamine. Phenol and boron nitride at 300° yield diphenylamine. β-Naphthol under similar conditions yields a product that has the composition of dinaphthylamine, but it differs from the latter in chemical and physical properties. It melts at 225°, and does not combine with acids (compare Abstr., 1891, 1003).

C. H. B.

Indothymol and Thymoquinone. By P. H. Bayrac (*Bull. Soc. Chim.* [3], **7**, 97—99).—*Indothymol*, $C_6H_2MePr<\begin{matrix}N\cdot C_6H_4\cdot NMe_2\\ |\\ O\end{matrix}$, is prepared as follows:—Nitrosodimethylaniline hydrochloride (18 grams) is dissolved in water (2 litres), heated to 35—40°, and reduced with zinc dust (15 grams). The solution of paramidodimethylaniline thus obtained is rapidly filtered into a 1 per cent. solution (1 litre) of soda containing thymol (15 grams), and potassium dichromate (10 grams) solution (500 c.c.) is then slowly added. On acidification with acetic acid, the indothymol separates, and is collected, rapidly washed with alcohol (90 per cent.), and crystallised from alcohol (95 per cent.). It forms long, anorthic, greenish needles, melting at 69·5°. It is insoluble in water, is not attacked by alkalis, gives a blue solution with alcohol, and is sparingly soluble in light petroleum, ether, and benzene, yielding violet solutions. Zinc and acetic acid reduce it, forming a leuco-base not yet isolated. Although not attacked by glacial acetic acid, indothymol is almost immediately decomposed by dilute mineral acids, with formation of derivatives of dimethylaniline and thymoquinone.

A theoretical yield of thymoquinone may be obtained by slightly heating indothymol (1 part) with 10 per cent. sulphuric acid (10 parts), and extracting the liquid with ether. The ethereal solution is evaporated, and the residue extracted with a mixture of alcohol and ether; on evaporating the liquid, pure thymoquinone separates. W. J. P.

Preparation of Carvacrol. By A. Reychler (*Bull. Soc. Chim.*, [3], **7**, 31—34).—Carvol hydrochloride (100 parts) is heated in a reflux apparatus with anhydrous zinc chloride (2 parts), and in order

to modify the violent reaction, glacial acetic acid (33 parts) is added. At 95°, hydrogen chloride begins to be evolved, and the reaction is completed at 110—120° in about 20 minutes; the major portion of the acetic acid is then distilled over, and the carvacrol separated from the remainder and from the zinc chloride by washing with water; it is then distilled, and the distillate is further purified by washing with dilute soda. The yield amounts to 90 per cent.

A solution of carvacrol in absolute alcohol does not affect the colour of ferric chloride, but the addition of a trace of water causes the solution to become green (Abstr., 1882, 1065). T. G. N.

Some Derivatives of Carvacrol. By A. Reychler (*Bull. Soc. Chim.* [3], **7**, 34—36).—Thymoquinone can be prepared by mixing solutions containing the calculated quantities of paracarvacrolsulphonic acid, obtained by the action of sulphuric acid on carvacrol, and potassium dichromate, and subsequently distilling the product of the oxidation in a current of steam. A yield of 68—70 per cent. is obtained.

Dimethylthymoquinol is prepared from thymoquinol by Nietzki's method (Abstr., 1878, 868), that is, by dissolving sodium in methyl alcohol, adding the quinol and the requisite amount of methyl iodide, and heating the mixture in a sealed tube for 12 hours. It is a yellowish oil of sp. gr. 0·998 at 22°, insoluble in water, and boils at 248—250°. It resembles the oil distilled from arnica root (this Journal, 1874, 377).

T. G. N.

Asbolin. By Béhal and Desvignes (*Compt. rend.*, **114**, 1541—1544).—The asbolin of Braconnot contains small quantities of acetic and butyric acids, but consists chiefly of catechol and a homocatechol. The latter boils at 251—252°, under a pressure of 750 mm., crystallises slowly when cooled, and afterwards melts at 46°. It is very soluble in water, and is even deliquescent. It is also readily soluble in alcohol, acetic acid, or benzene, but is almost insoluble in light petroleum. When purified by crystallisation from a mixture of benzene and light petroleum, it melts at 51°. With iron salts, chloroform, and potassium hydroxide it gives the same reactions as catechol.

The only known homocatechol is usually described as a liquid. The authors find, however, that the product obtained by the action of hydrogen iodide on cresol is really a solid melting at 51°, and boiling at 251—252° under a pressure of 750 mm. It is identical in all its properties with the homocatechol from asbolin. Homocatechol precipitates gelatin from its solution, and in this respect differs from catechol. Both compounds form yellow precipitates with quinine sulphate; when crystallised from alcohol, the catechol derivative melts at 157°, and the homocatechol at 167°. It is noteworthy that the two phenols found in asbolin are the lower homologues of the two phenols occurring in creosote. C. H. B.

Acetoneresorcinol. By H. Causse (*Compt. rend.*, **115**, 49—51).—Resorcinol (50 grams) is dissolved in pure acetone (100 grams) and concentrated hydrochloric acid (50 grams) is added. After some time,

heat is developed, and an amber-coloured, oily liquid separates. This is dissolved in alcohol, heated on a water bath, and reprecipitated by the addition of water; it again separates as an oily liquid, but after some days changes to a yellowish-white solid, which can be crystallised from dilute alcohol. It forms small, anhydrous prisms, and melts at 212—213°. It is insoluble in water, benzene, chloroform, and dry ether, but dissolves in alkalis and alkali carbonates.

This product is *acetoneresorcinol*, and when dried over sulphuric acid at 30° has the composition $C_{15}H_{16}O_4$. When distilled alone, it yields acetone, resorcinol, and a carbonaceous residue, and the same products are obtained when it is distilled with zinc powder in an atmosphere of hydrogen. When precipitated from alcohol by water, it forms a hydrate, $C_{15}H_{16}O_4 + H_2O$, which separates as a white, flocculent precipitate, which gradually becomes crystalline. It also combines with ether to form red, prismatic crystals, which lose ether when exposed to air.

Acetoneresorcinol, when heated with acetic anhydride, yields a diacetate, $C_{15}H_{24}O_4Ac_2$; this separates from ether in small, white prisms which melt at 126°, and are insoluble in cold alkalis or alkali carbonates, but dissolve with hydrolysis when heated. Benzoic chloride yields a dibenzoate, $C_{15}H_{14}O_4Bz_2$, which forms small, white crystals melting at 115°. Phosphorus oxychloride yields a phosphate, $C_{15}H_{14}O_4(H_2PO_3)_2$, which, when precipitated from alcohol by water and dried, forms a yellowish-white powder; this dissolves in caustic alkalis, and is reprecipitated by acetic acid. It follows from these results that acetoneresorcinol has the constitution $CMe_2(O\cdot C_6H_4\cdot OH)_2$.

C. H. B.

Sodium Pyrogallol. By DE FORCRAND (*Compt. rend.*, **115**, 46—48). —The sodium derivatives of pyrogallol were obtained (1) by dissolving sodium in an alcoholic solution of pyrogallol, and afterwards heating at 150°; and (2) by mixing aqueous solutions of sodium hydroxide and pyrogallol, evaporating, and heating at 150°. All the operations were conducted in an atmosphere of hydrogen. The first method gives practically colourless mono-, di-, and tri-sodium derivatives, which, however, always retain a certain quantity of alcohol; the second method gives unsatisfactory results with the mono- and di-derivatives, but yields trisodium pyrogallol almost pure and colourless. Measurements of the heat developed by the action of dilute sulphuric acid, a correction being made in those cases where alcohol is retained, lead to the following results:—

$C_6H_6O_3$ sol. + Na sol. = H gas + $C_6H_5NaO_3$ sol.	develops	+ 41·34 Cal.
$C_6H_5NaO_3$ sol. + Na sol. = H gas + $C_6H_4Na_2O_3$ sol.	„	+ 39·09 „
$C_6H_4Na_2O_3$ sol. + Na sol. = H gas + $C_6H_3Na_3O_3$ sol.	„	+ 35·66 „
$C_6H_6O_3$ sol. + Na_3 sol. = H_3 gas + $C_6H_3Na_3O_3$	„	+116·09 „

It is obvious that the value of the three phenolic functions dimin-

ishes regularly. The intermediate value is identical with that of ordinary phenol; the mean value of the first and third functions +38·5 Cal. is practically identical with the mean value in the case of resorcinol, +38·6 Cal. The mean value of the three functions, +38·70 Cal., is somewhat lower than that of phenol or the mean value for catechol, +39·02 Cal., but is greater than the mean value for resorcinol, and still greater than the mean value for quinol, +37·36 Cal.

C. H. B.

Conversion of Gallic Acid into Pyrogallol. By P. Cazeneuve (*Compt. rend.*, **114**, 1485—1487).—When gallic acid is mixed with about twice its weight of aniline, the mixture is at first liquid, but suddenly solidifies with development of heat. If the mass is heated at 120°, carbonic anhydride is evolved without any thermal disturbance, and the whole of the gallic acid can be decomposed at this temperature. As soon as evolution of gas ceases, the mixture is allowed to cool, and aniline pyrogallate separates in long needles melting at 55—56°. This salt is very unstable. In air at the ordinary temperature, or more rapidly in a vacuum, it loses aniline. When treated with benzene or toluene in the cold, aniline dissolves and pure pyrogallol is left.

Most liquid amines of the benzene series, such as orthotoluidine and the xylidines, as well as methylamine or quinoline, give similar results. Pyridine, which boils at 116·5, does not decompose gallic acid at this temperature, but when heated in sealed tubes at 130° there is progressive decomposition. The decomposition seems to be due to the intermediate formation of a gallate of the amine, less stable than gallic acid itself. Dimethylaniline, which does not combine with the gallic acid, does not decompose it even at 198°.

Pure pyrogallol melts at 132° (uncorr.), and not at 115° as usually stated.

C. H. B.

Action of Phosphorus Pentachloride on Methylhydrocotoïn and Methylprotocotoïn. By P. Bartolotti (*Gazzetta*, **22**, 498—503).—Ciamician and Silber (this vol., p. 62) have prepared a substance of the composition $C_9H_9Cl_3O_3$, by the action of phosphorus pentachloride on methylprotocotoïn or methylhydrocotoïn. The author treats methylhydrocotoïn (20 grams) with phosphorus pentachloride (120 grams), and then distils off the phosphorus compounds; the distillate and residue are now treated with water, and distilled in a current of steam. A small quantity of dichlorotoluene first passes over, and then a compound of the composition $C_9H_9Cl_3O_3$; the latter, after several crystallisations from alcohol, is obtained in minute, white needles melting at 130—131°. The molecular weight, determined by the cryoscopic method, is normal.

On heating the chlorinated compound (4 grams), dissolved in absolute alcohol (200 c.c.), in a reflux apparatus, and cautiously adding excess of sodium, a solution is obtained, from which trimethylphloroglucinol may be separated by distillation in a current of steam and subsequent crystallisation from alcohol. The chlorinated compound is, therefore, trichlorotrimethylphloroglucinol, and the product

of chlorination of hydrocotoïn and protocotoïn, $C_8H_7Cl_3O_2$, should be trichlorodimethylresorcinol.

Hydrocotoïn and protocoïn must be, therefore, considered as derivatives of dimethylphloroglucinol.

Commercial hydrocotoïn (100 grams) is methylated by dissolving it in methyl alcohol (200 c.c.) containing potash (32 grams); methyl iodide (100 grams) is now added, and the solution heated on the water bath for six hours. The methyl iodide and alcohol are then distilled off, and water added to the residue; the mass after a time solidifies, and is then treated with potash to remove unaltered hydrocotoïn and protocotoïn; the crude methylhydrocotoïn thus obtained is recrystallised from alcohol. W. J. P.

Derivatives of Isoapiole. By P. Bartolotti (*Gazzetta*, **22**, 558—566).—On boiling apiole with alcoholic potash, 70 per cent. of it is converted into the isomeric isoapiole; the remaining 30 per cent. is obtained as an oil. The author now shows this to be a mixture of the two isomerides; on subsequent treatment with alcoholic potash, it is completely converted into isoapiole.

Propenyldimethylapionol, $C_3H_5{\cdot}C_6H(OMe)_2(OH)_2$ [1 : 2 : 3 : 4 : 5 or 1 : 2 : 5 : 3 : 4], is prepared by heating isoapiole (5 grams), caustic potash (10 grams), and methyl alcohol (10 c.c.), in a closed tube at 140° for eight hours; a little hydrogen is produced. The mass is dissolved in water, and the solution, after extraction with ether to remove unchanged isoapiole, is acidified with sulphuric acid, and repeatedly extracted with ether; the ethereal solution is dried, the ether distilled off, and the oily residue distilled under 50 mm. pressure; the phenol (4·5 grams) thus obtained is a yellowish, thick oil, which solidifies after a long time. The *diacetyl* derivative is prepared by boiling the phenol (27 grams) with acetic anhydride (90 grams) and anhydrous sodium acetate (15 grams) in a reflux apparatus for some time; the acetic anhydride is then distilled off, the residue treated with water, and sodium carbonate, and the crude acetyl derivative (19 grams) crystallised from alcohol and benzene. It is finally obtained in colourless crystals, which are almost insoluble in cold ether, and melt at 125—126°. It is easily hydrolysed by alcoholic alkalis.

Dimethylapionolcarboxylic acid,

$$C_6H(OH)_2(OMe)_2{\cdot}COOH \text{ [1 : 2 : 3 : 4 : 5 or 2 : 3 : 1 : 4 : 5]},$$

is obtained by fusing apiolic acid (5 grams) with potash (25 grams) and a little water. The fusion must be stopped when a sample dissolved in water gives no precipitate on the addition of sulphuric acid. The product of the fusion is dissolved in water, acidified with sulphuric acid, and repeatedly extracted with ether; the ether is evaporated, the residue dissolved in ethyl acetate, and after long boiling with animal charcoal the solution is allowed to crystallise, when the new acid separates in small, colourless needles melting at 147—148°. It is soluble in water, alcohol, ether, benzene, and ethyl acetate, and is precipitated as an oil by light petroleum from its solution in benzene. It gives a blue colour with

ferric chloride, turning red with sodium carbonate. With lime water, the solution of the acid gives a violet colour, and ultimately a violet precipitate. Barium hydroxide gives a blue colour, and then a green precipitate. Potassium cyanide yields a red colour. Mercuric chloride gives a black precipitate after adding ammonia. Silver nitrate solution gives no indication, but metallic silver separates on adding ammonia. Lead acetate yields a milky-white precipitate. On the addition of potash, soda, or ammonia, and exposure to air, the solution of the acid turns black. No precipitate is obtained with barium or calcium chloride, copper nitrate, or ammonium salts.

A good yield (50 per cent.) of apiolic acid is obtained by dissolving isoapiole (4 grams) in boiling water (800 c.c.) and oxidising it by the gradual addition of a boiling alkaline solution (1600 c.c.) of potassium permanganate (16 grams). W. J. P.

Organic Halogen and Boron Derivatives. By C. Chabrié (*Bull. Soc. Chim.* [3], **7**, 18—31).—Ethyl sodiomalonate and carbon tetrachloride react to form *ethyl pentaneoctocarbonate*, according to the equation $4CHNa(COOEt)_2 + CCl_4 = C[CH(COOEt)_2]_4 + 4NaCl$. This compound is a syrupy liquid, forming an amorphous potassium salt, $C[CH(COOK)_2]_4$.

On heating sodium phenoxide with carbon tetrachloride in sealed tubes at 125°, aurine is formed, probably by the elimination of hydrogen chloride from the compound $CCl(C_6H_4{\cdot}OH)_3$, previously produced.

In addition to the fluorine derivatives previously described (Abstr., 1890, 558, 1053; 1891, 353), the author has prepared fluoroform by heating chloroform with silver fluoride. It is a colourless gas of characteristic odour, very slightly soluble in aqueous, but soluble in alcoholic potassium hydroxide, yielding potassium formate. The results of experiments on the antiseptic values of these fluorine derivatives are given.

On heating amorphous boron with the chlorides of carbon, with ethylene dibromide, and with tribromhydrin, the author found that in each case a replacement of carbon by boron occurred.

T. G. N.

Constitution of the Dihydroxythiobenzenes. By G. Tassinari (*Gazzetta*, **22**, 504—507).—The author has tried to prepare paranitrophenyl sulphide, $(NO_2{\cdot}C_6H_4)_2S$, by the action of paranitrothiophenol on salts of diazoparanitrobenzene under different conditions. The only product of the reaction which could be isolated was a small quantity of paranitrophenyl bisulphide. Analogous results were obtained with diazometanitrobenzene. On diazotising paraphenetidine, and adding hydrogen sulphide, yellow flocks separated; these decomposed very slowly at ordinary temperatures, but on heating for a few hours they yielded nitrogen and a resin. The precipitate, on extraction with alcohol, gave a small quantity of a substance which seemed to be "dioxythiophenetoïl" (ethoxyphenyl sulphide), $S(C_6H_4{\cdot}OEt)_2$,

melting at 51—58°, prepared from the dihydroxythiobenzene melting at 150—151°.

Parabromaniline, when diazotised and treated with hydrogen sulphide, yields a resin which, on extraction with alcohol, gives a fair yield of a crystalline compound. This substance, on crystallisation from carbon bisulphide, yields a very small quantity of red needles melting at 205—206°, probably consisting of a nitro-compound, and a crop of pearly-white scales, which melt at 112—113°. The latter substance is identical with the bromophenyl sulphide obtained from thioaniline or by brominating phenyl sulphide. This bromophenyl sulphide should be a dipara-derivative; hence the dihydroxythiobenzene, prepared by the action of sulphur chloride on phenol, is also a dipara-derivative. W. J. P.

Thiopinacone. By W. Spring and J. van Marseille (*Bull. Soc. Chim.* [3], **7**, 13—16).—When cinnamene dibromide is heated with an alcoholic solution of potassium hydrogen sulphide in sealed tubes at 120—130° for 30 hours, the contents separate into two layers, one of which is an uncrystallisable yellowish, oily liquid, of penetrating odour. This is free from bromine, and evolves hydrogen sulphide when warmed under reduced pressure. It could not be purified sufficiently for analysis, but on treating it with warm potassium hydroxide until potassium sulphide was no longer formed, a thiopinacoline, C_8H_8S, was obtained, probably by the separation of a molecule of hydrogen sulphide from the phenylthioglycol, $CHPh(SH)\cdot CH_2\cdot SH$, first formed. This thiopinacone is insoluble in water, slightly soluble in alcohol, and is soluble in a mixture of alcohol and ether, in light petroleum, in carbon bisulphide, and in benzene. Its sp. gr. at 16° is 1·0988, and on oxidation with chromic anhydride it yields benzoic acid, behaving in this respect like the pinacone, C_8H_8O (this Journal, 1877, ii, 614), but it differs from the isomeric xylylene sulphide (Abstr., 1884, 1313), which is crystalline, and can be distilled in a current of steam. T. G. N.

Carbaminethioacetophenone. By G. Marchesini (*Gazzetta*, **22**, i, 350—354).—Arapides (Abstr., 1889, 413) prepared carbaminethioacetophenone hydrochloride by prolonged heating of acetophenone thiocyanate with concentrated hydrochloric acid, but was unable to isolate the base, on account of its alleged instability. On mixing an aqueous solution of freshly prepared ammonium thiocarbamate with a saturated alcoholic solution of bromacetophenone in molecular proportion, and keeping the mixture cool, a white powder is precipitated, which, after drying in a vacuum, has the composition

$$COPh\cdot CH_2\cdot S\cdot CONH_2.$$

It melts at 120°, but subsequently solidifies, melting again at 204°. It dissolves in alcohol, but on heating and evaporating the solution, phenylhydroxythiazole (m. p. 204°) crystallises out. The *phenylhydrazine* derivative, $CPh(N_2HPh)\cdot CH_2\cdot S\cdot CONH_2$, prepared by agitating a mixture of carbaminethioacetophenone and phenylhydrazine,

in molecular proportion at the ordinary temperature, crystallises, when pure, in yellowish needles, melts at 130°, and dissolves in alcohol, ether, and chloroform. If a mixture of ammonium thiocarbamate and bromacetophenone is heated in a reflux apparatus in presence of alcohol, the principal product is phenylhydroxythiazole, whilst ammonium bromide and phenacyl sulphide are formed as intermediary products.

An aqueous solution of ammonium thiocarbamate gives the following reactions:—With lead salts, a brownish precipitate, changing to black, which evolves carbonic anhydride on treatment with cold nitric acid, and also hydrogen sulphide, on warming; with an excess of manganous sulphate, no precipitate is obtained in the cold, but on warming, a flesh-coloured precipitate, soluble in dilute nitric acid, is formed; on warming with barium chloride, a white precipitate, soluble with effervesence in dilute acids, is produced; with nickel sulphate, a black precipitate is obtained, resembling nickel sulphide, and soluble in dilute nitric acid; with copper sulphate, a brown precipitate, which blackens on heating, and dissolves in dilute nitric acid; with an excess of mercuric chloride, a dirty-white precipitate of the mercurous salt, $HgS{\cdot}CONH_2$, is formed; this rapidly darkens in the air, and dissolves in dilute hydrochloric or nitric acid. S. B. A. A.

Reduction of Coumarone. By H. Alexander (*Ber.*, **25**, 2409—2411).—*Hydrocoumarone*, C_8H_8O, is obtained by adding a boiling solution of coumarone in five times the quantity of absolute alcohol to sodium contained in a reflux apparatus, and then adding boiling alcohol until all the sodium is converted into sodium ethoxide. The product is mixed with water and the alcohol distilled off, when an oil passes over along with the alcohol, and can be precipitated by adding water to the distillate. The aqueous solution also contains some of the oil, which is separated by steam distillation. The oil is dissolved in ether, the ethereal solution washed with soda and then with water, and the ether evaporated. The residue is freed from coumarone by treatment with sulphuric acid, and finally the oil is dissolved in ether, dried, and fractionally distilled. It boils at 188—189°, is colourless, has a pleasant odour, and is soluble in ether, alcohol, chloroform, and carbon bisulphide, but insoluble in water. It is volatile with alcohol vapour, more easily with steam, is soluble in alkalis, and is not resinified by concentrated sulphuric acid. The sp. gr. at 23° = 1·06488. With ferric chloride and concentrated sulphuric acid, it gives a violet coloration.

On adding sulphuric acid to the aqueous liquid from which the hydrocoumarone has been separated, orthoethylphenol separates as an oil, which can be purified by steam distillation. It boils at 202—203° (uncorr.), turns yellow on exposure to the air, is easily soluble in alcohol, ether, and alkalis, and is very hygroscopic. With ferric chloride, it gives a greenish-grey coloration, and, when melted with potash, yields salicylic acid.

Orthoethylphenol is described as boiling at 206—207° (*Annalen*, **102**, 166; *Ber.*, **17**, 670). E. C. R.

Fluorescin, Galleïn, and Aurin. By J. Herzig (*Monatsh.*, **13**, 422—428).—The formation of colourless acetyl derivatives from quercetin, ethylquercetin, &c. (see Abstr., 1891, 1349), renders it possible that these are not derivatives of the original colouring matter, but of the corresponding leuco-derivative. Owing to the high molecular weights of these substances, the elementary analysis is insufficient to decide whether this is really the case, and the author has therefore examined the behaviour towards acetic anhydride of analogous compounds of lower molecular weight. Such a group is found in Baeyer's phthaleïns.

The melting points of acetylphenolphthaleïn and acetylphenolphthalin, on the one hand, and of acetylfluoresceïn and acetylfluorescin, on the other, are almost identical, and it appeared possible, therefore, that in the acetylation of fluoresceïn reduction might simultaneously take place, in which case the resulting compound would be identical with acetylfluorescin. On further investigation, this view was, however, found to be incorrect, the compounds, although similar in many respects, behaving quite differently towards alkalis.

Fluorescin was described by Baeyer as an oil, but may be obtained crystalline by triturating the syrup with acetic acid; it forms white needles melting at 125—127°, and becomes yellow in the air, when it has a melting point varying between 125° and 130°. On acetylation, it yields acetylfluorescin, which closely resembles acetylfluoresceïn in appearance, and melts at 200—202°. When treated with dilute alkali, however, it only dissolves in so far as it is hydrolysed, whilst acetylfluoresceïn dissolves readily, and, if the solution is quickly acidified, separates again unaltered.

The ethyl ethers of phenolphthalin and of fluorescin are readily obtained by saturating their alcoholic solutions with hydrogen chloride; the former crystallises from dilute alcohol in long needles which melt at 150—152° (uncorr.), and the latter from acetic acid in needles melting at 195—196°, and becoming yellow on exposure to air.

The acetyl derivatives of galleïn have already been examined by Buchka (*Annalen*, **209**, 261; Abstr., 1882, 59), who, by the reduction of galleïn, obtained, in addition to gallin, an intermediate hydrogalleïn. The author, in repeating these experiments on a smaller scale, was unable to obtain the latter compound, and found that acetylgalleïn and acetylgallin melt at 234—237° and 211—213° respectively, instead of 247—248° and 220°, as given by Buchka.

Results have also been obtained with acetylaurin and acetylrosolic acid, which are not in accordance with previous statements; further investigations on this point are in progress. H. G. C.

Influence of Nucleal Methyl on the Properties of Orthotoluidine. By A. Rosenstiehl (*Compt. rend.*, **115**, 180—182).—Weinberg's observations that the alkyl and amidated alkyl derivatives of orthotoluidine behave quite differently from the corresponding derivatives of aniline (this vol., p. 1078) may be explained by supposing that the former are virtually desmotropic, the methyl group wandering from the ortho-position either to the amido-group, or,

where this is fully substituted, to the position para- to the amido-group. Jn. W.

Action of Formaldehyde on Orthodimethyltoluidine. By H. Alexander (*Ber.*, **25**, 2408).—A base of the composition

$$NMe_2 \cdot C_6H_4 \cdot [CH_2]_3 \cdot C_6H_4 \cdot NMe_2,$$

is formed on heating orthodimethyltoluidine (9 grams) with solid formaldehyde (2 grams) and aqueous zinc chloride (0·5 per cent., 6 grams) for 18 hours at 170—180°. The product is distilled with steam, when the above base remains unvolatilised, any unaltered dimethyltoluidine being separated. It yields a sparingly soluble *platinochloride*, which melts above 200° with decomposition. The *base*, obtained by decomposing the platinochloride, distils as a colourless oil at 227—229° under a pressure of 40 mm., and is insoluble in water, but easily soluble in alcohol, ether, and chloroform. It has very feeble basic properties, and, with concentrated hydrochloric acid, yields a *hydrochloride*, which crystallises in beautiful, silky needles and easily decomposes with evolution of hydrogen chloride.

E. C. R.

Action of Benzyl Chloride on Unsymmetrical Metaxylidine. By Jablin-Gonnet (*Bull. Soc. Chim.* [3], **67**, 50—53).—*Methylbenzylmetaxylidine*, $C_6H_3Me_2 \cdot NMe \cdot C_7H_7$, is prepared by heating benzylmetaxylidine (3 mols.) and methyl iodide (2 mols.) in a reflux apparatus for 50 hours, neutralising the product with dilute sodium carbonate solution, extracting the supernatant, dark-brown liquid with benzene, and subsequently distilling it under reduced pressure. It is a yellowish liquid, insoluble in the ordinary solvents, and distils at 205—210°.

Acetylbenzylmetaxylidine, $C_6H_3Me_2 \cdot NAc \cdot C_7H_7$, is obtained similarly by the action of benzylmetaxylidine (2 mols.) on acetic chloride (1 mol.). It distils under a pressure of 10 mm. at 215—220° as a colourless liquid, rapidly turning yellow on exposure to air.

The ethyl derivative is prepared in like manner, and distils at 230—235°, but is less stable, and resinifies on exposure to air.

Benzoylbenzylmetaxylidine, $C_6H_3Me_2 \cdot NBz \cdot C_7H_7$, is formed on heating benzoic chloride (2 mols.) with benzylmetaxylidine (3 mols.) until hydrogen chloride is no longer evolved. After treatment with sodium carbonate and extraction with benzene, it distils under a pressure of 10 mm. at 240—245° as a greasy, straw-coloured liquid, which dissolves in benzene, ether, and alcohol; it is deposited from its solutions in white, prismatic crystals, melting at 85—86°.

Nitrobenzylmetaxylidine, $NO_2 \cdot C_6H_2Me_2 \cdot NH \cdot C_7H_7$, obtained by acting on benzylmetaxylidine with a mixture of sulphuric and nitric acids, is an orange-coloured substance, which is soluble in benzene, alcohol, and ether.

Benzylmetaxylidinesulphonic acid, $SO_3H \cdot C_6H_2Me_2 \cdot NH \cdot C_7H_7$, is obtained by the action on benzylmetaxylidine on sulphuric acid containing 10 per cent. sulphuric anhydride at 140—150°. It crystallises in prisms, and on oxidation is turned blue. T. G. N.

Action of Arsenious Chloride on Tertiary Aromatic Amines. By A. Michaelis and J. Rabinerson (*Annalen*, **270**, 139—147; compare Michaelis and Schenk, Abstr., 1891, 435).—*Dimethylamidophenylarsine oxide*, $NMe_2 \cdot C_6H_4 \cdot AsO$, is formed, together with hexamethyltriamidotriphenylarsine, when dimethylaniline (15 grams) is warmed with arsenious chloride (25 grams), and the mixture then treated with excess of concentrated soda; the filtered solution of the dimethylamidophenylarsine oxide is acidified with hydrochloric acid, and the base precipitated with sodium carbonate; it is a colourless powder, melts at 75°, and dissolves freely in chloroform and hot alcohol, but is insoluble in water. The *hydrochloride*, $C_8H_{10}N \cdot AsCl_2,HCl$, crystallises in slender, colourless needles, melts at 116°, and is readily soluble in water, but only sparingly in concentrated hydrochloric acid. The *hydrobromide* and the *hydriodide* were also prepared.

Dimethylamidophenylarsine sulphide, $NMe_2 \cdot C_6H_4 \cdot AsS$, prepared by passing hydrogen sulphide into an alcoholic solution of the corresponding oxide, crystallises from chloroform in colourless needles, melts at 187°, and is decomposed by hot hydrochloric acid with evolution of hydrogen sulphide.

Tetramethyldiamidoarsenobenzene, $NMe_2 \cdot C_6H_4 \cdot As{:}As \cdot C_6H_4 \cdot NMe_2$, can be obtained by reducing dimethylamidophenylarsine oxide with sodium amalgam in alcoholic solution; it separates from a mixture of alcohol and chloroform in the form of a yellow, semi-crystalline powder, melts at 202°, and is insoluble in water and alcohol, but readily soluble in chloroform and dilute acids. The *hydrochloride* is a red, crystalline compound, and, like the base, readily oxidises on exposure to the air.

Hexamethyltriamidotriphenylarsine, $As(C_6H_4 \cdot NMe_2)_3$, prepared by treating dimethylaniline with arsenious chloride at the ordinary temperature, crystallises from hot alcohol in long, colourless needles, melts at 240°, and is very readily soluble in chloroform, but only sparingly in cold alcohol.

Diethylamidophenylarsine oxide, $NEt_2 \cdot C_6H_4 \cdot AsO$, is a light yellow powder, melts at 58°, and dissolves freely in hot alcohol and in dilute mineral acids. The *dichloride*, $NEt_2 \cdot C_6H_4 \cdot AsCl_2$, crystallises in colourless needles, melts at 139°, and is very readily soluble in water, but only sparingly in concentrated hydrochloric acid. The *sulphide*, $NEt_2 \cdot C_6H_4 \cdot AsS$, forms colourless needles, melts at 155°, and dissolves freely in chloroform, but is insoluble in alcohol.

Tetrethyldiamidoarsenobenzene, $NEt_2 \cdot C_6H_4 \cdot As{:}As \cdot C_6H_4 \cdot NEt_2$, is a semi-crystalline, yellow powder melting at 180°; it is readily soluble in chloroform, but insoluble in alcohol. F. S. K.

Constitution of Nitrosoazo-Compounds. By C. Willgerodt (*J. pr. Chem.* [2], **46**, 128—141).—The author describes his most recent method for preparing dinitrosoazobenzene; it differs from that of Kehrmann and Messinger (this vol., p. 889) by the substitution of sodium hydrogen carbonate (1 mol.) for sodium acetate. The base obtained by the reduction of dinitrosoazobenzene (*loc. cit.*) is best isolated from the stannochloride by treating it with sodium hydroxide and recrystallising the precipitate from alcohol. This

base gives fluorescesent solutions in most alcohols, and in several other liquids besides those mentioned by Kehrmann and Messinger (*loc. cit.*). Analyses of the base indicate the formula $PhN_3{\cdot}C_6H_3{\cdot}NH_2$, which is confirmed by analysis of the *platinochloride*,

$$(C_{12}H_{10}N_4)_2,H_2PtCl_6,$$

and the conclusion is inevitable that it is amidophenylazimidobenzene. At the same time, the author does not admit that Kehrmann and Messinger are right in inferring from this, that dinitrosoazobenzene is nitrophenylazimidobenzene (*loc. cit.*) ; for he regards the reduction as consisting of a preliminary conversion of the azo-group in the dinitrosoazobenzene into a hydrazine group, followed by the elimination, as water, of the two hydrogen atoms thereof, together with the oxygen of one of the nitroso-groups, leaving an azimido-group.

The reduction of nitronitrosoazobenzene (5 grams) by heating it with stannous chloride (22 grams) in fuming hydrochloric acid (46 grams) and alcohol (200 c.c.) yields a base which crystallises in somewhat shorter and broader needles than those of amidophenylazimidobenzene, and melts at 183° (uncorr.); its solutions also fluoresce, but rather more strongly than those of amidophenylazimidobenzene. This base is being further examined.

Amidoparatolylazimidobenzene, $NH_2{\cdot}C_6H_3{<}\overset{N}{\underset{N}{|}}{>}N{\cdot}C_6H_4Me$, is formed when paratolyldinitrosoazobenzene (8 grams) is heated with stannous chloride (25·2 grams) in strong hydrochloric acid (50 grams) and alcohol (250 c.c.) for 20—25 minutes in a reflux apparatus, the stannochloride being afterwards decomposed by sodium hydroxide. It crystallises in pale-green, silky needles, melts at 212—213° (uncorr.), and dissolves sparingly in alcohol with a greenish-blue fluorescence ; its solutions in ether, benzene, and chloroform also fluoresce, but those in glacial acetic acid and carbon bisulphide do not. The *platinochloride*, $(C_{13}H_{12}N_1)_2,H_2PtCl_6$, was prepared. By acting on the base with reducing agents, a compound melting at 118°, and apparently identical with tolylazimidobenzene was obtained.

A controversial appendix has reference to Kehrmann's latest remarks (this vol., p. 1198). A. G. B.

Oxidation of Phenylhydrazine with Fehling's Solution. By H. Strache and M. Kitt (*Monatsh.*, **13**, 316—319).—E. Fischer has shown (*Annalen*, **190**, 101) that phenylhydrazine is oxidised by cold Fehling's solution with formation of benzene and aniline, whilst Strache has pointed out (this vol., p. 546) that when hot Fehling's solution is employed, the whole of the nitrogen evolved in the elementary state. In order to determine the quantity of alkaline cupric oxide required to bring about the oxidation in the latter case, the authors have allowed a solution of phenylhydrazine hydrochloride to run into a known volume of boiling Fehling's solution, until complete decolorisation ensued. The experiments showed that, for every molecule of phenylhydrazine employed, 3 mols. of cupric oxide were reduced to cuprous oxide, and

that neither aniline nor any other compound containing nitrogen was evolved, benzene and phenol being the other products of oxidation.

G. T. M.

Action of Cyanogen Chloride on Phenylhydrazine. By G. Pelizzari and D. Tivoli (*Gazzetta*, **22**, i, 226—236).—*Anilcyanamide*, $NHPh\cdot NH\cdot CN$, prepared by passing a current of cyanogen chloride through an ethereal solution of phenylhydrazine, is a red, oily compound very soluble in ether, alcohol, and benzene, but insoluble in water. It becomes altered on standing, and polymerises when slightly warmed. The *picrate*, $NHPh\cdot NH\cdot CN,C_6H_2(NO_2)_3\cdot OH$, crystallises from alcohol in slender needles, melts with decomposition at 198°, and dissolves readily in hot alcohol and benzene, but only very sparingly in ether and water. The *hydrochloride* is a white powder probably containing 2 mols. HCl when freshly prepared, but slowly losing hydrogen chloride on drying in a vacuum; it is freely soluble in alcohol, but insoluble in ether and benzene. It does not form a platinochloride or aurochloride, the metallic salts being reduced. It readily dissolves in water, but is at once converted into phenylsemicarbazide, which separates from the solution. When a well-cooled alcoholic solution of the hydrochloride is treated with ammonium hydrosulphide, an orange-yellow solution is formed, from which yellowish crystals of phenylsemithiocarbazide are deposited after a time.

Dianildicyandiamide is obtained by evaporating the ethereal solution of anilcyanamide to dryness on the water-bath. It separates from alcohol in pale rose-coloured, transparent, triclinic crystals, $a : b : c = 0{\cdot}9215 : 1 : 0{\cdot}5556$. The crystals contain 1 mol. of alcohol of crystallisation, which they lose at 100°, becoming dull and opaque. It melts with decomposition at 185°, and dissolves freely in hot alcohol, but is insoluble in ether. It readily dissolves in dilute acids, and is reprecipitated unchanged on the addition of potash. The *hydrochloride* $(PhN_2H_2CN)_2,HCl$, forms small, white crystals melting at 222°, readily soluble in water or alcohol. The *picrate*,

$$(PhN_2H_2CN)_2\cdot C_6H_3O(NO_2)_3,$$

crystallises from alcohol in lemon-yellow needles melting at 184°; it is very soluble in alcohol and moderately so in hot water. When heated on platinum foil, it melts and decomposes with violence. The constitution of dianildicyandiamide is probably

$$\begin{array}{l} NHPh\cdot N\text{---}C:NH \\ \quad\quad\ \ | \quad\quad\ \ | \\ \quad\quad CN \quad NH\cdot NHPh \end{array}$$

S. B. A. A.

Action of Phenylhydrazine on Carbamide. By L. Edeleanu (*Chem. Centr.*, 1892, i, 628).—*Phenylsemicarbazide*, $NH_2\cdot CO\cdot N_2H_3Ph$, is formed when phenylhydrazine is heated with carbamide; it crystallises in colourless laminæ, and melts at 172°. Another colourless substance, melting at 148—149°, and somewhat more soluble in alcohol, is obtained at the same time. A solution of phenylsemicarbazide gives a violet colour with mercuric chloride, and, after a time, a violet precipitate separates, which dyes silk violet; the colour is fast in water, and intensified by soap. Acids partially dissolve this

precipitate, yielding colourless solutions, from which the colouring matter is reprecipitated by alkali carbonates; concentrated alkalis, however, decompose it. If the mercury is removed from the filtrate from the mercuric chloride precipitate by means of hydrogen sulphide, a cherry-red liquid is obtained which, on evaporation, leaves a violet-black basic substance, soluble in alcohol with a violet colour and in strong sulphuric acid with a blue colour. With copper sulphate, phenylsemicarbazide solution gives a blue precipitate which behaves similarly to the mercury precipitate. The substance which melts at 148—149° also gives colouring matters with mercuric chloride and copper sulphate. A. G. B.

Inorganic Derivatives of Phenylhydrazine. By A. Michaelis (*Annalen*, **270**, 108—113).—General remarks on the papers by the author and Ruhl and the author and Oster (compare following abstracts). The results of the experiments here discussed, and of those previously published (Abstr., 1890, 617), go to show that sulphurous acid is an aldehyde acid of the constitution $H\cdot SO_2\cdot OH$; from the behaviour of the phosphorus compounds, it is probable that phosphorous acid has the constitution $H\cdot PO(OH)_2$, and phosphenous acid the constitution $H\cdot PO(OH)\cdot Ph$. F. S. K.

Thionyl Chloride and Aromatic Hydrazines. By A. Michaelis and J. Ruhl (*Annalen*, **270**, 114—122; compare Abstr., 1890, 617). —Thionylparatolylhydrazone crystallises in long, yellow needles, and melts at 112°.

Thionyl-α-naphthylhydrazone, $C_{10}H_7\cdot NH\cdot N{:}SO$, prepared by treating α-naphthylhydrazine with thionyl chloride in ethereal solution, crystallises from hot alcohol in yellowish-red plates, and melts at 100°. The corresponding β-compound crystallises from hot alcohol in yellowish-red plates, and melts at 136—139° with decomposition.

Thionylmethylphenylhydrazone, $NMePh\cdot N{:}SO$, is formed when thionylaniline (Abstr., 1891, 715) is treated with methylphenylhydrazine in acetic acid solution; it crystallises from hot alcohol in small, yellow needles, melts at 77°, and is readily decomposed by alkalis, yielding methylphenylhydrazine and a sulphite.

Thionylisobutylphenylhydrazone, $C_4H_9\cdot NPh\cdot N{:}SO$, prepared in like manner, is a yellow liquid having a peculiar penetrating odour.

Thionylbenzylphenylhydrazone, $C_7H_7\cdot NPh\cdot N{:}SO$, crystallises from hot light petroleum in yellow prisms, and melts at 65°.

Thionylethylenephenylhydrazone, $C_2H_4(NPh\cdot N{:}SO)_2$, prepared by treating ethylenephenylhydrazine with thionyl chloride or with thionylaniline, crystallises from hot alcohol in lustrous, yellow plates melting at 121—123°. F. S. K.

Action of the Chlorides of Phosphorus, Arsenic, Boron, and Silicon on Aromatic Hydrazines. By A. Michaelis and F. Oster (*Annalen*, **270**, 123—139).—When phenylhydrazine is treated with phosphorus trichloride in well-cooled ethereal solution, a semi-solid compound is formed free from chlorine, and which has, in all probability, the constitution $NHPh\cdot NH\cdot P{:}N\cdot NHPh$; when this

substance is treated with water, it is gradually converted into a yellowish, seemingly amorphous powder, which is the *dihydrazide* of phosphorous acid, $OH{\cdot}P(N_2H_2Ph)_2$. The last-named compound sinters and partially decomposes at 80°, and is readily soluble in chloroform, ethyl acetate, and alcohol, but insoluble in benzene, ether, and light petroleum; it is only very slowly decomposed by boiling alkalis, but readily by acids, and it reduces Fehling's solution in the cold; when treated with benzaldehyde, it is decomposed with formation of benzylidenephenylhydrazone, and, on oxidation with yellow mercuric oxide in chloroform solution, it is converted into a red, vitreous substance which melts at 94—95°.

Phosphenylphenylhydrazine, $PPh{:}N{\cdot}NHPh$, prepared by treating phenylhydrazine with phosphenyl chloride in well-cooled ethereal solution, crystallises from ethyl acetate in small plates, melts at 152°, and is readily soluble in chloroform, but only sparingly in cold ethyl acetate, ether, and alcohol. It reduces Fehling's solution on warming, and is readily decomposed by acids, but is more stable towards boiling alkalis; when boiled with water, it is gradually converted into phenylhydrazine phosphenite (see below).

Phosphenylparatolylhydrazone, $PPh{:}N{\cdot}NH{\cdot}C_6H_4Me$, crystallises in small, colourless or yellowish prisms, melts at 162°, and is converted into tolylhydrazine phosphenite by boiling water.

Phosphenylbenzylphenylhydrazone, $PPh{:}N{\cdot}NPh{\cdot}C_7H_7$, crystallises from a mixture of ether and chloroform in colourless needles, melts at 141°, and is readily soluble in alcohol, ethylacetate, and chloroform, but more sparingly in ether, and insoluble in water; it reduces Fehling's solution on boiling, and is decomposed into its components by acids, but is very stable towards boiling alkalis; on prolonged boiling with water, it is converted into benzylphenylhydrazine phosphenite.

Phenylhydrazine phosphite, $(N_2H_3Ph)_2,H_3PO_3$, crystallises in nacreous plates, melts at 121°, and is readily soluble in water and alcohol. The *acid salt*, N_2H_3Ph,H_3PO_3, forms large plates, melts at 118°, and dissolves freely in alcohol and water.

Phenylhydrazine phosphenite, N_2H_3Ph,PH_2PhO_2, crystallises in long, colourless prisms, melts at 135°, and is readily soluble in alcohol and boiling water, but only very sparingly in cold water. The *paratolylhydrazine* salt, $N_2H_3{\cdot}C_6H_4Me,PH_2PhO_2$, crystallises in slender, colourless needles, melts at 148°, and is readily soluble in alcohol and hot water, but only sparingly in cold water.

Phenylhydrazine paratolylphosphenite, $N_2H_3Ph,PH_2O_2{\cdot}C_6H_4Me$, prepared from its components, melts at 161°, crystallises in slender needles, and is readily soluble in hot alcohol, but only sparingly in boiling water.

Benzylphenylhydrazine phosphenite, $N_2H_2Ph{\cdot}C_7H_7,PH_2PhO_2$, crystallises in long, colourless prisms, and melts at 108°.

Phosphorylphenylhydrazide, $PO(N_2H_2Ph)_3$, prepared by treating phosphorus oxychloride with phenylhydrazine in well-cooled ethereal solution, crystallises from hot alcohol in small, colourless needles, melts at 196°, and turns brown on exposure to the air; it dissolves freely in alcohol and ethyl acetate, but is insoluble in chloroform,

ether, and benzene; it reduces Fehling's solution on warming, and is readily decomposed by alkalis and acids.

Phosphoryltolylhydrazide, $PO(N_2H_2\cdot C_6H_4Me)_3$, crystallises in slender, colourless needles, melts at 189°, and quickly turns yellow on exposure to the air.

Thiophosphorylphenylhydrazide, $PS(N_2H_2Ph)_3$, separates from ethyl acetate in slender, colourless needles, melts at 154°, and is readily soluble in alcohol, but insoluble in chloroform, ether, and benzene; when heated with water, it is slowly converted into phosphorylphenylhydrazide with evolution of hydrogen sulphide.

A compound of the composition $AsCl_3.3N_2H_3Ph$ is formed when phenylhydrazine is treated with arsenic trichloride in ethereal solution; it is a colourless, amorphous powder, turns black at 190°, decomposes completely at 236°, and dissolves in water with decomposition.

Boron trichloride and phenylhydrazine combine under the same conditions to form a compound of the composition $BCl_3,3N_2H_3Ph$; this substance decomposes completely at 242°, and is readily soluble in water, but insoluble in chloroform and ethyl acetate.

Silicon tetrachloride and phenylhydrazine combine to form a yellow, crystalline, unstable substance which is free from chlorine.

F. S. K.

Parathiophenylhydrazine and Thionylthioaniline. By J. Ruhl (*Annalen*, **270**, 148—154; compare Abstr., 1891, 301).—*Thionylthioaniline*, $S(C_6H_4\cdot N{:}SO)_2$, prepared by treating thioaniline with thionyl chloride in benzene solution, crystallises in reddish-yellow prisms, melts at 110°, and decomposes on exposure to the air.

Parathiophenylhydrazine (*loc. cit.*) melts at 114°, and is only sparingly soluble in cold chloroform and cold benzene; its hydrochloride crystallises in small prisms, and melts at 208—209° with decomposition; its sulphate melts at 219° with decomposition, and crystallises from hot dilute sulphuric acid in prisms. The *oxalate*, $S(C_6H_4\cdot N_2H_3)_2,C_2H_2O_4$, is a crystalline powder. The *acetyl* derivative, $S(C_6H_4\cdot N_2H_2Ac)_2$, crystallises from hot chloroform in small, colourless needles, and melts at 170—171° with decomposition.

Benzylidenethiophenylhydrazone, $S(C_6H_4\cdot NH\cdot N{:}CHPh)_2$, separates from alcohol in crystals, and melts at 185°.

Acetophenonethiophenylhydrazone, $S(C_6H_4\cdot NH\cdot N{:}CMePh)_2$, is a colourless crystalline powder, and melts at 170° with decomposition.

Pyruvic acid thiophenylhydrazone, $S(C_6H_4\cdot NH\cdot N{:}CMe\cdot COOH)_2$, is a yellow, amorphous substance.

Tetraphenylthiodithiosemicarbazide, $S(C_6H_4\cdot N_2H_2\cdot CS\cdot NHPh)_2$, prepared by treating thiophenylhydrazine with phenylthiocarbimide in alcoholic solution, crystallises from hot alcohol in slender needles, and melts at 180—182° with decomposition.

Thionylthiophenylhydrazone, $S(C_6H_4\cdot NH\cdot N{:}SO)_2$, is a yellow, crystalline powder, melts at 187°, and is only sparingly soluble in hot alcohol.

F. S. K.

Imidazoles and the Constitution of Glyoxaline. By W. Marckwald (*Ber.*, **25**, 2354—2373).—The author has shown that when phenyl- and methyl-acetalylthiocarbamide are treated with acid, alcohol

is eliminated, and mercaptans of the imidazole series are formed, according to the equation $CS<^{NHR}_{NH\cdot CH_2\cdot CH(OEt)_2} = \begin{matrix} HS\cdot C\cdot NR\cdot CH \\ \| \quad\quad \| \\ N\text{---}CH \end{matrix}$ + 2EtHO. When these are oxidised, hydrogen is substituted for the hydrosulphide group, with formation of sulphuric acid and ν-phenyl- and ν-methylimidazole are obtained. The latter is identical with methylglyoxaline. This reaction confirms Japp's formula for glyoxaline.

The author has prepared glyoxaline synthetically by this method, and also a number of substitution products of imidazole analogous to ν-phenylimidazole.

Amidoacetal, from which the compounds described below are obtained, is best prepared by employing a large excess of ammonia, namely, 20 parts of saturated alcoholic ammonia to 1 part of chloracetal, heating the mixture at 125—130° for 10 hours; 50 per cent. of the theoretical yield of the primary base can thus be obtained. If less ammonia is employed, large quantities of secondary and tertiary bases are formed.

Diacetalylthiocarbamide, $CS[NH\cdot CH_2\cdot CH(OEt)_2]_2$, is obtained on heating amidoacetal with a slight excess of carbon bisulphide on the water-bath. Hydrogen sulphide is evolved, and an oil is obtained which slowly solidifies. It crystallises from light petroleum in well-formed, transparent crystals, melts at 54°, and is extremely soluble in most organic solvents.

Acetalylcarbamide, $NH_2\cdot CO\cdot NH\cdot CH_2\cdot CH(OEt)_2$, is obtained by warming amidoacetal hydrochloride in concentrated aqueous solution with a slight excess of potassium cyanate. It crystallises from hot water, melts at 105°, and is easily soluble in hot water and alcohol, moderately in cold water and chloroform, and sparingly so in ether and light petroleum.

μ-Imidazolone, $\begin{matrix} CO\cdot NH\cdot CH \\ | \quad\quad | \\ NH\text{---}CH \end{matrix}$, is obtained by warming acetalylcarbamide in aqueous solution with a few drops of sulphuric acid. The sulphuric acid is precipitated by barium carbonate and the filtrate evaporated on the water-bath and allowed to crystallise. μ-Imidazolone is easily soluble in hot water, sparingly so in other solvents, and decomposes above the boiling point of concentrated sulphuric acid. The properties of the compound are in accordance with the formula given above and also with the tautomeric formula $\begin{matrix} HO\cdot C\cdot NH\cdot CH \\ \| \quad\quad \| \\ N\text{---}CH \end{matrix}$. It has both feeble basic and acid properties, but the salts cannot be obtained pure. When alcohol is added to a solution of the hydrochloride, a solid salt is precipitated which is too hygroscopic to be analysed. The platinochloride behaves in a similar way. Gold chloride and ammoniacal silver solution are reduced with precipitation of the metal. The author could not obtain glyoxaline from this compound either by distillation over zinc dust or by reduction with hydriodic acid. When treated with phosphorus pentachloride, it is completely carbonised.

μ-Imidazolyl mercaptan, $\begin{matrix}HS\cdot C\cdot NH\cdot CH\\ \|\quad\quad\quad\|\\ N\text{——}CH\end{matrix}$.—An aqueous solution of equivalent quantities of amidoacetal and potassium thiocyanate is evaporated, the residue extracted with absolute alcohol, the alcohol distilled off, and the syrup which remains heated at 140°. A reaction then takes place with evolution of alcohol and the formation of μ-imidazolyl mercaptan. This melts at 222°, but begins to decompose at 210°, and is easily soluble in hot water and alcohol, less so in cold water and only sparingly in ether, benzene, and chloroform. It is easily soluble in alkalis, and forms salts both with acids and bases. The *hydrochloride* is crystalline and moderately soluble in alcohol. The *sulphate* is precipitated in crystals from alcoholic solutions. The *platinochloride* is brick-red and has the composition $(C_3H_4SN_2)_2PtCl_4$. The solution of the mercaptan gives precipitates with salts of the heavy metals.

μ-Imidazolylmethyl sulphide, $\begin{matrix}MeS\cdot C\cdot NH\cdot CH\\ \|\quad\quad\quad\|\\ N\text{——}CH\end{matrix}$, is obtained by allowing an alcoholic solution of the mercaptan and methyl iodide to remain for a day and then precipitating the solution with potash. It melts at 139°, boils at 251—252° without decomposition, is somewhat easily soluble in water, easily in most organic solvents, and gives well-crystallised salts with mineral acids. The *platinochloride* forms orange-yellow crystals, is sparingly soluble, and melts at 187° with decomposition. The *picrate* crystallises in beautiful, yellow needles, and melts at 186°. A crystalline silver derivative of the composition $C_4H_5SN_2Ag$ was also obtained.

Glyoxaline is obtained by warming imidazolyl mercaptan (6 grams) with 10 per cent. nitric acid (160 c.c.) on the water-bath and, after the first action is over, heating for half an hour at 100° and evaporating to dryness. The base is obtained by converting the product into the silver salt, decomposing this with hydrogen sulphide, and evaporating the aqueous solution; the syrupy residue distils at 257°, and solidifies in the receiver. It melts at 88°. The *aurochloride* forms yellow needles, is sparingly soluble in water and alcohol, and decomposes at 230°.

Acetalylparatolylthiocarbamide, $C_6H_4Me\cdot NH\cdot CS\cdot NH\cdot CH_2\cdot CH(OEt)_2$, obtained from amidoacetal and paratolyl isothiocyanate, is an oil which slowly crystallises, melts at 54—56°, is precipitated as an oil from all organic solvents, and is very easily soluble. The *picrate*, $C_{14}H_{22}N_2SO_2.C_6H_2(NO_2)_3\cdot OH$, crystallises in lemon-yellow crystals, melts at 205°, and is sparingly soluble in all solvents.

ν-Paratolylimidazolyl-μ-mercaptan, $\begin{matrix}HS\cdot C\cdot N(C_7H_7)\cdot CH\\ \|\quad\quad\quad\|\\ N\text{————}CH\end{matrix}$, is obtained by boiling the preceding compound with dilute hydrochloric acid for about an hour in a reflux apparatus. It crystallises in silvery leaflets, melts at 205° with incipient decomposition, and is sparingly soluble in cold water, more so in hot water. It gives precipitates with salts of the heavy metals. The *platinochloride* is thrown down from an alcoholic solution as an orange, crystalline precipitate and has the composition $(C_{10}H_{10}N_2S)_2PtCl_4$.

Tolylimidazolyl methylsulphide.—When the preceding mercaptan dissolved in alcohol is treated with the equivalent quantity of methyl iodide and the mixture allowed to remain, a clear solution is obtained, from which ether precipitates white needles of the hydriodide of the above base. The *hydriodide* melts at 95°, and is very easily soluble in water and alcohol. The *base* is obtained by decomposing this salt with alkali; it is insoluble in water, easily soluble in most other solvents, melts at 90°, and sublimes in beautiful, fan-like crystals. It yields well crystallised salts with mineral acids. The *picrate* melts at 140°. The *platinochloride*, an orange-yellow, crystalline precipitate, is sparingly soluble in water, more easily so in alcohol. The base combines with methyl iodide to form a sulphinium base. The latter crystallises in white needles, melts at 162°, and is sparingly soluble in ether and cold water, easily so in hot water and alcohol.

ν-Paratolylimidazole, $\begin{matrix} CH\cdot N(C_7H_7)\cdot CH \\ \| \qquad\qquad\quad \| \\ N \text{———} CH \end{matrix}$, is obtained by warming tolylimidazolyl mercaptan with 16 times the quantity of 10 per cent. nitric acid on the water-bath, and decomposing the salt thus obtained with alkali. The product is extracted with ether, and the ethereal solution dried by potassium hydroxide and distilled; the base passes over at 285°, and solidifies in the receiver to pale-yellow crystals. It is sparingly soluble in water, very easily in other solvents, and has an intense mushroom-like odour. With mineral acids, it gives well-crystallised salts which are easily soluble in water. The *picrate* crystallises in golden needles, melts at 179°, and is insoluble in cold water and alcohol. The *platinochloride*, $(C_{10}H_{10}N_2)_2,H_2PtCl_6$, is a yellow, crystalline precipitate, and is sparingly soluble in water and alcohol. When concentrated silver nitrate is added to an alcoholic solution of the base, a white, crystalline compound of the composition

$$C_{10}H_{10}N_2,AgNO_3$$

is obtained. An *ammonium base* is formed when tolylimidazole dissolved in chloroform is allowed to remain for a day with methyl iodide; on adding ether to the solution, it is precipitated in slender, white needles. It melts at 90°, and is sparingly soluble in water, easily so in alcohol, chloroform, and benzene.

Acetalylmetaxylylthiocarbamide, $C_6H_3Me_2\cdot NH\cdot CS\cdot NH\cdot CH_2\cdot CH(OEt)_2$, is obtained from amidoacetal and asymmetrical metaxylylthiocarbamide as a viscid oil, which solidifies in a few days. It melts at 53°, and is very easily soluble in most organic solvents, but only sparingly in water or light petroleum. The *picrate* crystallises in lemon-yellow needles, melts at 147—148°, and is sparingly soluble in water, light petroleum, cold alcohol, and ether, more easily in hot alcohol, chloroform, and benzene.

ν-Metaxylylimidazolyl-μ-mercaptan, $\begin{matrix} HS\cdot C\cdot N\cdot(C_8H_9)\cdot CH \\ \| \qquad\qquad\quad \| \\ N \text{———} CH \end{matrix}$, is obtained by the action of hydrochloric acid on the preceding mercaptan. It crystallises from hot water in nacreous leaflets, melts at 192°, and is sparingly soluble in cold water, more easily in cold alcohol, carbon bisulphide, and benzene, and easily in hot water and alcohol and in

chloroform and acetic acid. It yields precipitates with salts of the heavy metals. The *platinochloride*, $C_{11}H_{12}N_2S,PtCl_4$, is obtained in scarlet crystals, melts above 250°, is almost insoluble in water and ether, but somewhat soluble in alcohol and easily so in chloroform.

ν-Metaxylylimidazolyl-μ-methylsulphide, is obtained by treating the mercaptan with methyl iodide and decomposing the hydriodide with ammonia. It is an oil which cannot be distilled without decomposition. The base yields well-crystallised salts. The *hydriodide* melts at 165°, and is very easily soluble in water and alcohol, sparingly so in most other solvents. The *aurochloride* is obtained in greenish-yellow crystals. The *platinochloride* forms golden-yellow crystals, melts at 209° with decomposition, and is moderately soluble in alcohol. The *picrate* melts at 158—159°. The *iodide of the sulphinium base* is obtained by allowing the base to remain for a day with excess of methyl iodide. It forms white crystals, melts at 169—170°, and is easily soluble in chloroform, sparingly in other solvents.

ν-Metaxylylimidazole, $\begin{matrix} HC\cdot N(C_8H_9)\cdot CH \\ \| \qquad\qquad | \\ N\text{———}CH \end{matrix}$, is obtained by oxidising the mercaptan with nitric acid, as an oil which distils at 279° without decomposition, and solidifies after a time. It melts at 32°, and is sparingly soluble in water, but very easily in most other solvents. The salts are easily soluble. The *aurochloride* forms greenish-yellow crystals, and melts at 164—165°. The *platinochloride* crystallises in long, slender, orange needles, sinters at 208°, melts with decomposition at a slightly higher temperature, and is very sparingly soluble in water, more easily so in alcohol. The *picrate* crystallises in deep-yellow needles, melts at 159°, and is sparingly soluble in most solvents, but more easily in chloroform.

Wohl and Marckwald (*Ber.*, **22**, 578) obtained a carbamide of the formula $NHPh\cdot CS\cdot NH\cdot CH_2\cdot CH(OH)\cdot OEt$, by treating acetylphenylthiocarbamide with concentrated sulphuric acid. With acids, this carbamide yielded salts which were not derived from the carbamide itself, but from a base formed from it by the withdrawal of the elements of water. This base has the formula $CS<^{-NPh-}_{NH\cdot CH_2}>CH\cdot OEt$, or $HS\cdot C<^{-NPh-}_{N\cdot CH_2}>CH\cdot OEt$, and when set free from its salts takes up water and is reconverted into the thiocarbamide. A similar carbamide of the formula $C_6H_3Me_2\cdot NH\cdot CS\cdot NH\cdot CH_2\cdot CH(OH)\cdot OEt$ is obtained by dissolving acetalylmetaxylylthiocarbamide in well-cooled, concentrated sulphuric acid and pouring the mixture on to ice. On adding ammonia, an oil is obtained which dissolves on shaking with ether, and crystallises on evaporation of the solvent. It crystallises from dilute alcohol in white needles, melts at 94—95°, is insoluble in water, sparingly soluble in cold alcohol, but easily in hot alcohol and most other solvents. The carbamide dissolves in acids, but the salts were not obtained crystalline. With platinic chloride, it gives a scarlet, crystalline double salt. A *picrate*, which, however, as was to be expected, is derived from a base of the formula

$$\begin{matrix} CS\cdot N(C_8H_9)\cdot CH\cdot OEt \\ | \qquad\qquad | \\ NH\text{———}CH_2 \end{matrix} \quad \text{or} \quad \begin{matrix} HS\cdot C\cdot N(C_8H_9)CH\cdot OEt \\ \| \qquad\qquad | \\ N\text{———}CH_2 \end{matrix},$$

is obtained when picric acid is added to a hot, dilute alcoholic solution of the carbamide. It crystallises in lustrous, golden needles, melts at 143—144°, and is very easily soluble in chloroform, somewhat easily in benzene, but only sparingly in most other solvents.

α-Naphthylthiocarbimide is obtained by heating di-α-naphthylthiocarbamide with concentrated phosphoric acid. It crystallises from dilute alcohol in long needles, melts at 58°, and gradually reddens on exposure to air.

Acetalyl-α-naphthylthiocarbamide, obtained by treating the preceding compound with amidoacetal in alcoholic solution, forms slender, white crystals, melts at 112°, and is easily soluble in ether, benzene, light petroleum, and acetic acid, but more sparingly in cold alcohol.

ν-α-Naphthylimidazole-μ-mercaptan, $\begin{matrix}HS\cdot C\cdot N(C_{10}H_7)\cdot CH\\ \|\qquad\qquad\quad \|\\ N\text{———}CH\end{matrix}$, forms white crystals, melts at 242° with decomposition, and is sparingly soluble in water and alcohol, but more easily in other solvents. The *silver derivative*, $C_{13}H_9N_2SAg$, is obtained as a white, crystalline precipitate on adding silver nitrate to an alcoholic solution of the mercaptan.

ν-α-Naphthylimidazolyl-μ-methylsulphide melts at 127°, is easily soluble in alcohol and ether, and yields well crystallised salts with mineral acids. The *hydriodide* is obtained as a syrup which slowly crystallises, separates as an oil from all solvents, and when boiled with water yields the free base. The *platinochloride*, $(C_{14}H_{12}N_2S)_2,H_2PtCl_6$, is obtained in yellow crystals which are sparingly soluble in water, alcohol, and ether. The *aurochloride* is a red, amorphous precipitate. The *picrate* crystallises from alcohol in long yellow needles, melts at 162°, and is sparingly soluble in water, alcohol, and ether.

ν-α-Naphthylimidazole, $\begin{matrix}CH\cdot N(C_{10}H_7)\cdot CH\\ \|\qquad\qquad\quad \|\\ N\text{———}CH,\end{matrix}$ distils undecomposed above the boiling point of mercury, melts at 62°, is insoluble in water, easily soluble in other solvents, and yields easily soluble and well crystallised salts. The *platinochloride* forms orange crystals, is sparingly soluble, and melts above 300°. The *picrate* crystallises in yellow needles, melts at 194—195°, and is sparingly soluble. The *methiodide*, $C_{13}H_{10}N_2,MeI$, melts at 195°, is insoluble in ether, and somewhat soluble in alcohol and water. E. C. R.

Formation of Oxazolines. By S. Gabriel and A. Neumann (*Ber.*, **25**, 2383—2388).—The method consists in eliminating a molecule of hydrogen chloride from a β-chlorethylimido-ether, when a μ-alkyloxazoline is formed.

Benzimido-β-chlorethyl ether, $NH{:}CPh\cdot O\cdot CH_2\cdot CH_2Cl$.—The *hydrochloride* of this compound is obtained by treating an ice-cold mixture of benzonitrile (5 grams) and ethylenechlorhydrin (4 grams) with dry hydrogen chloride for about half an hour. The solid crystalline mass thus obtained is ground in a mortar, washed with dry benzene, and dried, first over sulphuric acid, then at 60—70°; the yield is quantitative. It melts at 147—148° with decomposition. When warmed in aqueous solution, it is decomposed, and yields ammonium chloride and chlorethyl benzoate, $C_6H_5\cdot COOC_2H_4Cl$. The

latter, which is separated either by steam distillation or by extraction with ether, boils at 254—255° under a pressure of 749 mm. When the hydrochloride is heated alone above its melting point, it yields ethylene chloride and benzamide. The *picrate* of benzimidochlorethyl ether is obtained in sparingly soluble, yellow needles on adding a cold solution of picric acid to a cold, dilute, aqueous solution of the hydrochloride. It is dried over sulphuric acid, and decomposes on warming. The *platinochloride*, $(C_9H_{10}ONCl)_2,H_2PtCl_6$, forms orange-yellow scales, and melts at 180° to a reddish-brown liquid. The *free* benzimidochlorethyl ether is obtained in oily drops on adding an alkali to the cold aqueous solution of the hydrochloride, and can be extracted by shaking with ether; it is very easily decomposed. When the cold ethereal solution is allowed to evaporate over sulphuric acid, an oil is obtained which becomes semi-solid after a time, and consists of crystals of benzimidochlorethyl ether (m. p. 147—148°) and μ-phenyloxazoline. When the ethereal solution of benzimidochlorethyl ether is evaporated on the water-bath, it is converted almost quantitatively into β-chlorethylbenzamide, $C_2H_4Cl{\cdot}NH{\cdot}COPh$, which melts at 102—103°; and on boiling the latter compound with sodium hydroxide, a good yield of phenyloxazoline is obtained. A more convenient way of obtaining the phenyloxazoline, but one which gives a poorer yield, is to add normal soda (21 c.c.) to benzimidochlorethyl ether hydrochloride (2·2 grams), and, after diluting with water, to distil the mixture with steam. The distillate, which contains benzonitrile and phenyloxazoline, is mixed with hydrochloric acid, and after removing the benzonitrile by agitation with ether, the aqueous solution is saturated with alkali, and the phenyloxazoline extracted by ether.

Acetimido-β-chlorethyl ether, $NH{:}CMe{\cdot}O{\cdot}C_2H_4Cl$.—The *hydrochloride* is formed on saturating a well-cooled mixture of acetonitrile and ethylenechlorhydrin with dry hydrogen chloride; it is a viscous oil which deposits colourless needles after a time. The *picrate* crystallises in golden, six-sided leaflets, and melts at 106—107°. When the above oil is dissolved in water and the solution warmed, it is converted into chlorethyl acetate, $CH_3{\cdot}COOC_2H_4Cl$, which boils at 141—143° under a pressure of 754 mm. The same compound is obtained in small quantities when the hydrochloride is decomposed with soda and then subjected to steam distillation. The distillate also contains small quantities of methyloxazoline. The latter is separated as picrate, after extracting the chlorethyl acetate with ether, by adding picric acid to the aqueous solution. The *picrate* crystallises in yellow needles, and melts at 157—158°.

E. C. R.

Instability of Carboxyl in Phenolic Acids. By P. Cazeneuve (*Compt. rend.*, **115**, 182—185).—The conversion of gallic acid into pyrogallol at comparatively low temperatures, under the influence of aromatic amines (this vol., p. 1314), is a particular case of what appears to be a general property of phenolic acids, a number of which are now shown to be decomposed when heated with aniline.

Gallic acid splits up at 115°, protocatechuic acid at 180°, salicylic

acid at 220°, but benzoic acid is not affected. The stability of the acids decreases therefore as the number of phenolic hydroxyls increases.

Dibromosalicylic acid decomposes at 180°, dichlorosalicylic at 200°, dibromogallic acid at 80°, but tribromobenzoic acid is not affected. Orsellinic (methyldihydroxybenzoic) acid splits up at 110°, and dibromorsellinic acid loses carbonic anhydride when heated in water to 100°, and presumably, therefore, at a lower temperature when heated in aniline. Thus the stability of the acids is decreased by the nucleal substitution of halogen or alkyl.

Finally, salicylic acid is less stable than parahydroxybenzoic acid, and this in turn than the meta-acid, which is scarcely affected when heated with aniline in a sealed tube at 240°. Jn. W.

Orthoparadinitrophenylglycollic Acid. By L. Pratesi (*Gazzetta*, **22**. i, 242—250.—The author has previously mentioned that when phenylglycollic acid is nitrated with nitric acid of 48° Baumé, the product is 2 : 4-*dinitrophenylglycollic* acid. It crystallises from water in large, colourless, or pale, yellowish-green prisms, melts at 147—148° in the air, and at 86° under water. It is sparingly soluble in cold water (1 part in 353 of water at 21°), moderately in cold alcohol, benzene, ether, and acetic acid. It is converted by potash into the corresponding dinitrophenol melting at 113—114°. The ammonium salt crystallises in colourless plates containing $\frac{1}{2}$ mol. H_2O, and is very soluble in water; it gradually loses weight in a vacuum. The *potassium* salt contains $\frac{1}{2}$ mol. H_2O; it is almost colourless, very soluble in water, turns yellow at 107°, and decomposes at a higher temperature. It deflagrates when rapidly heated. The *sodium* salt contains 1 mol. H_2O; it is very soluble in water, and deflagrates on heating. The *barium* salt crystallises in thin plates containing $3\frac{1}{2}$ mols. H_2O; it is moderately soluble in boiling water, and decomposes when heated above 100°. The *copper* salt contains 5 mols. H_2O; the *silver* salt is anhydrous. The *ethyl* derivative is a white, crystalline compound, which melts at 77—78°, and is sparingly soluble in cold alcohol. The *methyl* derivative melts at 73°. The *amide* is obtained by leaving either the methyl or ethyl derivative in contact with concentrated ammonia for 24 hours. It crystallises from alcohol in white needles melting at 182—184°. It is moderately soluble in boiling alcohol, but insoluble in water. With nitrous acid, it yields 2 : 4-dinitrophenylglycollic acid.

Phenylglycollic, paracresolglycollic, thymolglycollic, salicylglycollic, and resorcinoldiacetic acids are readily converted into the corresponding phenols by fusing the acid (1 part) with potash (4 parts) and water (1 part). The yield is in general almost theoretical, but if the heating is carried too far, the lateral groups become oxidised. Ortho- and para-nitrophenylglycollic acids are much more readily hydrolysed. S. B. A. A.

Derivatives of Phenylglycocine and Orthotolylglycocine. By C. A. Bischoff and A. Hausdörfer (*Ber.*, **25**, 2270—2280).—A good yield of ethyl anilidoacetate (Meyer, this Journal, 1876, i, 372)

is obtained from ethyl chloracetate (100 grams) by heating it on the water-bath for an hour with aniline (150 grams). After repeated crystallisation from light petroleum, it melts at 58°, and boils at 273—274°. It gives phenylglycocine on treatment with aqueous alkali. When phenylglycocine is treated at the ordinary temperature with acetic anhydride, acetylphenylglycocine, melting at 194—195° (compare Rebuffat, Abstr., 1887, 1108; Paal and Otten, Abstr., 1890, 1415), is obtained; whilst if the reagents are heated together in an oil-bath at 160—180°, a small quantity of diphenyl-$\alpha\gamma$-diketopiperazine (Abstr., 1890, 1332) is also formed.

Phenylimidodiacetic anhydride, $NPh<^{CH_2\cdot CO}_{CH_2\cdot CO}>O$, is obtained by heating phenylimidodiacetic acid (2 grams) with acetic anhydride (3 grams) on the water-bath; when crystallised from benzene and acetone, it forms tablets, melts at 148°, and is sparingly soluble in light petroleum; water converts it into the acid, and when heated with aniline at 150° the anilide melting at 211—213° (Abstr., 1889, 1014) is produced. Dimethylparatoluidine (Hübner, *Annalen*, **224**, 336) is formed when phenylimidodiacetic acid is distilled.

Diphenylhydantoïn, $NPh<^{CH_2CO}_{CO\cdot NPh}$, is prepared by dropping phenylglycocinanilide (5 grams) into a solution of sodium (0·5 gram) in absolute alcohol (12 grams), and adding carbonyl chloride (4·5 grams) dissolved in benzene to the cooled mixture; the product is then shaken with water, and the oil which separates, probably the salt $NHPh\cdot CO\cdot CH_2\cdot NPh\cdot COOEt$, is converted into the hydantoïn by means of concentrated aqueous potash; on the addition of acid, it separates as an oil, which subsequently solidifies. It crystallises from alcohol in colourless plates, and melts at 139°.

Ethyl orthotoluidoacetate (Ehrlich, Abstr., 1883, 593) is obtained by heating ethyl chloracetate with orthotoluidine for $1\frac{1}{2}$ hours on the water-bath; it is a colourless oil, boiling at 281° (746 mm.), and having a sp. gr. of 1·058 at 20°/20°. When tolylglycocinetoluidide (Ehrlich, *loc. cit.*) is distilled, orthoditolylcarbamide is formed. If dissolved in benzene and treated with a solution of carbonyl chloride (2 mols.) in the same solvent, a white precipitate separates. On heating this at 170—175° for three hours, and then distilling in a current of steam, a residue is left, which is insoluble in alcohol and ether; when this is dissolved in chloroform and precipitated with ether, *orthoditolylhydantoïn* is obtained as a colourless, crystalline powder, melting at 270—275°.

Acetylorthotolylglycocine, $C_6H_4Me\cdot NAc\cdot CH_2\cdot COOH$, is formed when orthotolyglycocine (5 grams) is heated with acetic anhydride (4 grams) for two hours, in a reflux apparatus on an oil-bath at 180°; it crystallises from dilute alcohol in colourless, elongated tables, melts at 210—212°, and is sparingly soluble in cold ether, and in hot and cold water, readily in hot 50 per cent. alcohol and glacial acetic acid.

Diorthotolyl-$\alpha\gamma$-diketopiperazine (Abstr., 1889, 1012) is produced by heating orthotolylglycocine with acetic anhydride for four hours at 138°. It is not attacked by zinc and hydrochloric acid, by sodium amalgam and acetic acid, or by alcoholic ammonia at 150°, but it is

converted into orthotolylglycocine when treated with a solution of sodium in amyl alcohol.

Ammonium orthotolylimidodiacetate, $C_6H_4Me{\cdot}N(CH_2{\cdot}COONH_4)_2$, is obtained by saturating an alcoholic solution of the acid with ammonia; it melts at 158—160° with the evolution of ammonia and alcohol, and is readily soluble in water, sparingly in cold alcohol, but readily so in the hot liquid.

Orthotolylimidodiacetamide, $C_6H_4Me{\cdot}N(CH_2{\cdot}CONH_2)_2$, is formed when the acid is dissolved in aqueous ammonia, and the solution evaporated; it forms white, lustrous leaflets, melts at 163—164°, and is sparingly soluble in cold water and alcohol, readily so in the hot liquids, as well as in ether.

Orthotolylimidodiacetimide, $C_6H_4Me{\cdot}N<\begin{matrix}CH_2{\cdot}CO\\CH_2{\cdot}CO\end{matrix}>NH$, is produced by heating ammonium orthotolylimidodiacetate in an oil-bath at 165° for 4—5 hours; it crystallises from alcohol in white, lustrous prisms, melts at 145—146°, and is sparingly soluble in water and ether. A. R. L.

Paratolylglycocine and its Derivatives. By C. A. Bischoff and A. Hausdörfer (*Ber.*, **25**, 2280—2290) —Ethyl paratoluidoacetate (Meyer, this Journal, 1176, i, 402) is prepared by heating ethyl chloracetate (100 grams) with paratoluidine (175 grams) for an hour on the water-bath; it crystallises in the asymmetric system, $a : b : c = 0{\cdot}3878 : 1 : 0{\cdot}2595$.

Schwebel (*Ber.*, **10**, 2407) described a compound melting at 166—168° as paratolylglycocine, which he obtained by Meyer's method (*loc. cit.*); later Schwebel (*Inaug. Diss.*, Berlin, 1878) isolated an isomeride melting at 118—119°, which he supposed to be orthotolylglycocine. Meyer, however, subsequently showed (*Ber.*, **14**, 1323) that the latter was not orthotolylglycocine; he considered the compound of higher melting point to be paratolylglycocine, and that of lower melting point to be a polymeride (see below). Various observers have from time to time noted the abnormal behaviour of the so-called paratolylglycocine (compare, for example, Heumann, Abstr., 1891, 928). The authors now find that when the above described ethyl salt is treated with concentrated aqueous potash, and the solution cautiously neutralised, the compound melting at 118—119° is precipitated; it gives the indigo reaction on heating it with potassium hydroxide at 300°, and is accordingly the true paratolylglycocine. The so-called paratolylglycocine melting at 166—168° is obtained when chloracetic acid (25 grams) and paratoluidine (57·5 grams) are suspended in water (800 c.c.), and the mixture boiled in a reflux apparatus for three hours; it is recrystallised from water, and a certain quantity of paratolylglycocine may be isolated from the aqueous mother liquor. The compound does not give the indigo reaction, but when it is heated with sodium carbonate solution, paratoluidine separates, and paratolylimidodiacetic acid (see below) can be isolated from the alkaline solution; it has, therefore, the constitution, $C_6H_4Me{\cdot}N<\begin{matrix}CH_2{\cdot}COOH\\CH_2{\cdot}COO{\cdot}NH_3{\cdot}C_6H_4Me\end{matrix}$, assigned by

Meyer to the true paratolylglycocine (see above). It also gives *paratolylimidodiacetic ditoluide*, $C_6H_4Me{\cdot}N(CH_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4Me)_2$, melting at 213—215°, when heated with paratoluidine at 200°.

Paratolylimidodiacetic acid, $C_6H_4Me{\cdot}N(CH_2{\cdot}COOH)_2$, is prepared by heating together on the water-bath paratolylglycocine (10 grams), chloracetic acid (6 grams), and anhydrous sodium carbonate (10 grams), in aqueous solution. On adding concentrated hydrochloric acid to the hot solution until the precipitate at first produced redissolves, and allowing it to cool, the compound separates in lustrous needles. It loses water at 100°, and melts completely at 120°; it is soluble in most solvents except light petroleum, and its crystals contain ½ mol. H_2O.

Paratolylglycocine, when treated with acetic anhydride, gives the acetyl derivative described by Paal and Otten (Abstr., 1890, 1415). The compounds previously obtained by the authors (Abstr., 1890, 1284) by the action of acetic anhydride on the supposed paratolylglycocine (m. p. 166—168°) are now found to be acetylparatoluidine (m. p. 147°) and paratolylimidodiacetic monamide (m. p. 222°). Diparatolyl-$\alpha\gamma$-diketopiperazine, melting at 254—255° (Abenius, Abstr., 1890, 269), is obtained, together with *diparatolyl-$\alpha\delta$-diketopiperazine*, on heating paratolylglycocine; the δ-compound is separated from the $\alpha\gamma$-compound by means of its greater solubility in alcohol; it melts at 185°, and gives paratolylimidodiacetic monotoluidide (Abstr., 1890, 1285) on treatment with alcoholic potash, and the *amide*, $C_6H_4Me{\cdot}N{<}\begin{matrix}CH_2{\cdot}CO{\cdot}NH_2\\CH_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4Me\end{matrix}$, identical with the compound previously described as paratolylglycinimide (Abstr., 1890, 1284), on boiling with alcoholic ammonia.

Diparatolylhydantoïn, $C_6H_4Me{\cdot}N{<}\begin{matrix}CH_2{\cdot}CO\\CO{\cdot}N{\cdot}C_6H_4Me\end{matrix}$, is obtained when paratolylglycocine toluidide (5 grams) is treated with a 20 per cent. solution of carbonyl chloride (25 grams), and the mixture heated at 140° for an hour; when the residue left on evaporating the solvent is crystallised from alcohol, the pure compound is obtained in colourless leaflets melting at 175°; it is sparingly soluble in light petroleum, but readily so in other solvents.

Chloracetylparatolylglycocine toluidide,

$$C_6H_4Me{\cdot}N(CO{\cdot}CH_2Cl){\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4Me,$$

is produced on mixing paratolylglycocine toluidide dissolved in benzone with an equal weight of chloracetic chloride; it forms slender, white needles, melts at 158°, and is readily soluble in alcohol, but insoluble in light petroleum. A. R. L.

Derivatives of α-Amidopropionic Acid. By C. A. Bischoff and A. Hausdörfer (*Ber.*, **25**, 2298—2313).—Of the three diphenyl-$\alpha\gamma$-dimethyl-$\beta\delta$-diketopiperazines (Nastvogel, Abstr., 1890, 1160), that melting at 183·5° is, in accordance with Bischoff's scheme for distinguishing the geometrically isomeric substituted succinic acids, the para-modification, and that melting at 172—173° the anti-modification, since the former is convertible into the latter (*loc. cit.*; see

also below). When α-bromopropanilide melting at 99° (45·6 grams) is heated on the water-bath for four hours with potassium hydroxide (11·2 grams) dissolved in alcohol (200 c.c.), *α-ethoxypropanilide*, NHPh·CO·CHMe·OEt, which crystallises in white, nodular aggregates of needles and melts at 62—63°, is obtained, together with the above-mentioned para- and anti-diphenyldimethyldiketopiperazines. When paradiphenyl-αγ-dimethyl-βδ-diketopiperazine (5 grams) is boiled with 10 per cent. aqueous potash (150 c.c.) and the acid obtained on acidifying the solution heated at 120°, antidiphenyl-αγ-dimethyl-βδ-diketopiperazine is formed, but Nastvogel's diphenyldimethyldiketopiperazine melting at 144—146°, which is perhaps a structural isomeride, is not present.

Ethyl α-orthotoluidopropionate, $C_6H_4Me{\cdot}NH{\cdot}CHMe{\cdot}COOEt$, is formed on heating ethyl α-bromopropionate with orthotoluidine at 100°; it is a yellowish oil of sp. gr. 1·047 at 20°/20°, and boils at 277—278°. The corresponding acid has been described by Gerson (Abstr., 1887, 260); the *acetyl derivative*, $C_6H_4Me{\cdot}NHAc{\cdot}CHMe{\cdot}COOH$, crystallises in white leaflets, and melts at 177°.

Ethyl α-paratoluidopropionate crystallises in large tables, and melts at 35°. The *acid* obtained from it by hydrolysis with potash forms silvery scales, melts at 158°, and is soluble in both acids and alkalis; the *acetyl derivative* melts at 166°. When the acid is quickly distilled, it decomposes for the most part into acetylparatoluidine melting at 217°; if, however, it is slowly heated at 200—210° in a current of carbonic anhydride, or, better, with acetic anhydride, the portion of the product insoluble in alkalis consists of two isomeric *diparatolyl-αγ-diketopiperazines*, $C_6H_4Me{\cdot}N<\begin{matrix}CHMe{\cdot}CO\\CO{\cdot}CHMe\end{matrix}>N{\cdot}C_6H_4Me$; of these, the para-modification crystallises in colourless, translucent needles, melts at 248°, and is very easily soluble in chloroform, whilst the anti-modification forms prisms, melts at 191—195°, and is somewhat less soluble in chloroform.

Ethyl α-naphthylidopropionate, obtained by heating ethyl α-bromopropionate with α-naphthylamine at 165°, crystallises from alcohol in small, nodular crusts, and melts at 65·5°. The corresponding *acid*, obtained by hydrolysing the ethyl salt with potash, as well as by heating together α-bromopropionic acid, α-naphthylamine, and water, crystallises from alcohol in small, lustrous leaflets, and melts at 160—161°; on distilling it, ethyl-α-naphthylamine, boiling at 303°, passes over.

Ethyl β-naphthylidopropionate is produced, together with ββ-dinaphthylamine, when ethyl α-bromopropionate is heated at 165° for two hours with β-naphthylamine; it crystallises in prisms, and melts at 84°. *β-Naphthylido-α-propionic acid* is obtained from the ethyl salt, and also by heating together α-bromopropionic acid, β-naphthylamine, and water; it melts at 170—171°, and is insoluble in cold water, but soluble in hot alcohol. When the acid is distilled, ethyl-β-naphthylamine (see Bamberger and Müller, Abstr., 1889, 888) passes over at 307—310°. On boiling the acid with acetic anhydride, the *acetyl derivative* melting at 197—199° is obtained from the portion soluble in alkali, whilst *β-dinaphthyl-αγ-dimethyl-βδ-diketopiperazine*,

$C_{10}H_7 \cdot N < \begin{matrix} CHMe \cdot CO \\ CO \cdot CHMe \end{matrix} > N \cdot C_{10}H_7$, melting at 269°, is isolated from the portion insoluble in alkali. A. R. L.

Derivatives of α-Amidobutyric Acid. By C. A. Bischoff and N. Mintz (*Ber.*, **25**, 2314—2325).—When α-anilidobutyric acid (Duvillier, Abstr., 1881, 87) is quickly distilled, propylaniline passes over. *Acetanilidobutyric acid*, NPhAc·CHEt·COOH, is obtained when α- anilidobutyric acid (5 grams) is heated in a reflux apparatus on the water-bath with acetic chloride (8 c.c.) ; the product is dissolved in aqueous sodium carbonate, the solution extracted with ether and acidified with hydrochloric acid, when the acid separates as a resinous mass, but after remaining for a week in the cold it becomes crystalline. It separates slowly from its solution in benzene in prisms, melts at 118°, is sparingly soluble in light petroleum and cold water, but readily in hot water and most other solvents. The two diphenyl-αγ-diethyl-βδ-diketopiperazines melting at 260° and 145°, which are described by Nastvogel (Abstr., 1890, 1160), may be distinguished as the para- and anti-modifications respectively.

Ethyl α-orthotoluidobutyrate, $C_6H_4Me \cdot NH \cdot CHEt \cdot COOEt$, prepared by heating orthotoluidine with ethyl α-bromobutyrate on the water-bath for 4—5 hours, is a bright-yellow liquid of sp. gr. 1·019 at 20°/20°, boiling at 278°. The corresponding *acid* forms long prisms melting at 84°, gives an *acetyl* derivative, $C_6H_4Me \cdot NAc \cdot CHEt \cdot COOH$, melting at 114—116°, and when distilled yields propylorthotoluidine boiling at 230°.

Ethyl α-paratoluidobutyrate, formed by heating paratoluidine with ethyl α-bromobutyrate at 105°, boils at 278—280°, and has a sp. gr. at 20°/20° = 1·011. The corresponding acid crystallises in leaflets, melts at 153—156°, and gives propylparatoluidine (Hori and Morley, Trans., 1891, 35) on distillation; when heated with acetic anhydride in a sealed tube at 160°, the acid yields an *acetyl* derivative melting at 149°, whilst from a portion of the product insoluble in alkali two isomeric *diparatolyl-αγ-diethyl-βδ-diketopiperazines*, melting at 256° and 204—210° respectively, are isolated.

Ethyl α-naphthylidobutyrate, $C_{10}H_7 \cdot NH \cdot CHEt \cdot COOEt$, produced by heating ethyl α-bromobutyrate with α-naphthylamine at 165°, crystallises from alcohol in white, silky needles melting at 80°. The corresponding acid crystallises from dilute alcohol in small tablets, melts at 126° with the evolution of gas, and, when heated at 200°, gives *propyl α-naphthylamine*, boiling at 316—318°, the *acetyl derivative* of which melts at 93—94°.

Ethyl β-naphthylidobutyrate is obtained, together with β-dinaphthylamine (m. p. 172°), when ethyl α-bromobutyrate is heated with β-naphthylamine at 165° ; it crystallises in prisms, melts at 69°, and boils at 264° (43 mm.). The corresponding acid melts at 158°, and when distilled yields *propyl-β-naphthylamine*, boiling at 322—324°.

A. R. L.

Anilidoisobutyric Acids. By C. A. Bischoff and N. Mintz (*Ber.*, **25**, 2326—2334).—Ethyl anilidoisobutyrate, melting at 30° (Abstr., 1891, 828), is the β-compound, $NHPh \cdot CH_2 \cdot CHMe \cdot COOEt$,

and not the α-derivative as stated; its formation from aniline and ethyl α-bromisobutyrate is in harmony with Bischoff's dynamical hypothesis (Abstr., 1890, 723). When the product of the action is heated with potash in a current of steam, β-anilidoisobutyric acid (Tiemann, Abstr., 1883, 1993) passes over, together with one-fifth of its weight of the α-acid (see below), and can be separated by fractional precipitation with hydrochloric acid. *β-Acetanilidoisobutyric acid*, $NPhAc{\cdot}CH_2{\cdot}CHMe{\cdot}COOH$, melts at 174°. When β-anilidoisobutyric acid is distilled, aniline and a *lactone* melting at 120° are formed; the latter has one of the formulæ $NPh<\begin{matrix}CH_2{\cdot}CHMe{\cdot}CO\\CO-CMe_2-O\end{matrix}$ or $NPh<\begin{matrix}CH_2{\cdot}CHMe{\cdot}CO\\CO{\cdot}CHMe{\cdot}CH_2\end{matrix}>O$.

α-Anilidoisobutyric acid melts at 140—142°, and gives isopropylaniline (Pictet and Crépieux, Abstr., 1888, 689) on distillation.

A. R. L.

Toluidoisobutyric Acids. By C. A. Bischoff and N. Mintz (*Ber.*, **25**, 2334—2345).—When orthotoluidine (250 grams) is heated on the water-bath with ethyl α-bromisobutyrate (195 grams), and the mixture subsequently heated at 150—160° for nine hours, the portion of the product boiling between 250° and 295° solidifies on being cooled, and separates from ether in asymmetrical crystals, $a:b:c = 0{\cdot}8623:1:0{\cdot}5041$, melting at 57°, and having the composition of an ethyl orthotoluidoisobutyrate. When this compound is heated with potash in a current of steam, two acids, melting at 60—62° and at 108—110° respectively, are isolated by fractional precipitation with hydrochloric acid. The former is probably α-orthotoluidobutyric acid; the latter is the corresponding β-acid, and yields an *acetyl derivative*, $C_6H_4Me{\cdot}NAc{\cdot}CH_2{\cdot}CHMe{\cdot}COOH$, which melts at 219°, and is sparingly soluble in hot ether. On distillation, orthotoluidine and the *lactone* $C_6H_4Me{\cdot}N<\begin{matrix}CH_2{\cdot}CHMe\\CO{\cdot}C_3H_6{\cdot}O\end{matrix}>CO$, melting at 95°, are obtained.

When paratoluidine (260 grams) is heated at 160—170° for 10 hours with ethyl α-bromisobutyrate, the portion of the product boiling below 295° consists of a compound having the composition of an ethyl paratoluidoisobutyrate, whilst the small portion boiling above 295° is the lactone (m. p. 170°) described below. The ethyl salt solidifies on being cooled, and crystallises from ether in monosymmetric crystals, $a:b:c = 0{\cdot}81055:1:0{\cdot}67955$; $\beta = 79°\ 30'$; and melts at 36°. When treated with potash in a current of steam, two acids are isolated on fractional precipitation with hydrochloric acid. *β-Paratoluidoisobutyric acid* melts at 194—196°, gives an *acetyl* derivative,

$$C_6H_4Me{\cdot}NAc{\cdot}CH_2{\cdot}CHMe{\cdot}COOH,$$

melting at 206°, and decomposes on distillation into paratoluidine and the *lactone*,

$$C_6H_4Me{\cdot}N<\begin{matrix}CH_2-CHMe{\cdot}CO\\CO{\cdot}CHMe{\cdot}CH_2{\cdot}O\end{matrix}\quad\text{or}\quad C_6H_4Me{\cdot}N<\begin{matrix}CH_2{\cdot}CHMe\\CO{\cdot}CMe_2{\cdot}O\end{matrix}>CO,$$

melting at 170°. *α-Paratoluidoisobutyric acid* melts at 149—150°, and

on distillation isopropylparatoluidine (compare Hori and Morley, Trans., 1891, 34) passes over at 230—231°. It yields an acetyl derivative melting at 144—146°. A. R. L.

Synthesis of Unsaturated Nitriles. By E. Fiquet (*Bull. Soc. Chim.* [3], **7**, 11—13).—A mixture of benzaldehyde with cyanacetic acid in molecular proportion is heated at 180°, and the crystalline mass which forms on cooling is treated with alcohol. The product, *benzylidenecyanacetic acid*, $C_{10}H_7NO_2$, melts at 180°. It does not combine with bromine, and, when treated with potassium hydroxide, yields benzaldehyde and potassium acetate and carbonate, with evolution of ammonia; if heated above its melting point, it gives off carbonic anhydride and yields cinnamonitrile, distilling at 252—254°. From these reactions, the author infers that benzylidenecyanacetic acid has the constitution CHPh:C(CN)·COOH, which the determination of the molecular weight by Raoult's method confirms. Metatoluic, cinnamic, and acetic aldehydes yield analogous compounds.

This acid differs from its isomeride described by Carrick (Abstr., 1890, 1270; this vol., p. 1086), in that the latter has entirely different reactions. T. G. N.

Xylenedisulphonic Acids. By E. Pfannenstill (*J. pr. Chem.* [2], **46**, 152—157).—Metaxylene disulphonic acid [$Me_2 : (SO_3H)_2 = 1 : 3 : 2 : 4$] was prepared by Wischin (Abstr., 1891, 73) by the direct sulphonation of metaxylene. The author has prepared it from crystalline metaxylenesulphonic acid [$Me_2 : SO_3H = 1 : 3 : 4$] by heating it (3 parts) with chlorosulphuric acid (4 parts) at 150°, neutralising it with chalk, converting it into potassium salt, and then into the disulphonic chloride in the usual manner. The acid is obtained on heating the disulphonic chloride with water in a sealed tube at 140°. The *potassium* (with 2 mols. H_2O), *sodium* (with 3 mols. H_2O), *ammonium*, *barium* (with 3 mols. H_2O), *lead* (with 3 mols. H_2O), *magnesium*, *zinc*, *cadmium*, and *copper* salts were prepared. The *ethyl* salt crystallises in laminæ, and is nearly insoluble in water, but soluble in alcohol. The disulphonic chloride melts at 129°, and the amide at 249°. The dihydroxymetaxylene obtained by fusing the potassium salt with potassium hydroxide melts at 149—150° (Wischen, *loc. cit.*).

Metaxylenedisulphonic acid [$Me_2 : (SO_3H)_2 = 1 : 3 : 2 : 5$], corresponding with the uncrystallisable metaxylenesulphonic acid ($Me_2 : SO_3H = 1 : 3 : 2$; this Journal, 1877, ii, 601), is prepared from crude xylene by shaking it with strong sulphuric acid, which dissolves the meta- and ortho-xylene; after separating the crystallisable acid as far as possible, the sulphuric acid mother liquor, containing the uncrystallisable acid, is neutralised with barium hydroxide, and the barium salt further sulphonated with chlorosulphuric acid as above; the product is then treated with ether, whereby the metaxylenedisulphonic chlorides may be separated, the crystalline variety being less soluble. The *acid* crystallises in needles, and its *potassium*, *barium*, and *lead* salts are easily soluble and easily crystallised. The *chloride* is a brown, viscid oil which does not crystallise. The *amide*

is more soluble in water than that of the crystalline acid, and melts at 210°.

Orthoxylenedisulphonic acid can be prepared in a similar manner; it could not be crystallised. The *potassium* salt, with x mols. H_2O, the *barium* salt, with 3 mols. H_2O, and the *lead* salt, with 3 mols. H_2O, were prepared.

The *disulphonic chloride* crystallises in prisms, melts at 79°, and dissolves in ether, chloroform, and carbon bisulphide. The *amide* melts at 239°, and is sparingly soluble in water. The corresponding dihydroxyorthoxylene was prepared, but its constitution was not settled; 4 : 6 is the most probable orientation of the sulphonic groups in the sulphonic acid.

A paraxylenedisulphonic acid has been prepared by Holmes (Abstr., 1891, 1374); it agrees in the main with that prepared by the author, who, however, finds that the disulphonic chloride melts at 74—75° (not 72—74°), that the amide melts at 250° (not 294°), and that the barium salt crystallises with 3 mols. H_2O. A. G. B.

Nitro-β-naphthols. By F. Gaess (*J. pr. Chem.* [2], **46**, 160).—By a printer's error, the orientation of the nitro-β-naphthols described in the author's last paper (this vol., p. 1229), was wrongly given; "1′ : 2′-nitronaphthol" should read "1′ : 2-nitronaphthol," and "2 : 2′-nitronaphthol" should read "3′ : 2-nitronaphthol."

A. G. B.

Derivatives of Naphthylglycocines. By C. A. Bischoff and A. Hausdörfer (*Ber.*, **25**, 2290—2298).—Ethyl α-naphthylidoacetate, $C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}COOEt$, is prepared by heating ethyl chloracetate (50 grams) and α-naphthylamine (99 grams) with anhydrous sodium carbonate (45 grams) in a reflux apparatus, adding water, extracting with ether, and fractionating under diminished pressure; it is a yellowish oil, insoluble in water, but miscible with alcohol; it boils at 244° (5 mm.).

α-Naphthylglycocine-α-naphthylidoacetic acid,

$$C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}CO{\cdot}N(C_{10}H_7){\cdot}CH_2{\cdot}COOH,$$

is obtained when α-dinaphthyl-αγ-diketopiperazine (Abstr., 1890, 1309) is heated with alcoholic potash; it decomposes easily, melts at 180°, and is sparingly soluble in cold water and light petroleum, readily in ether and hot alcohol. Acetyl-α-naphthylglycocine (Forte, Abstr., 1890, 901) is prepared from α-naphthylglycocine and acetic chloride at the ordinary temperature.

The compound obtained by heating α-naphthylglycocine at 273° melts at 275°; it is not a piperazine derivative, but has, perhaps, the constitution $(C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}CO)_2O$; it gives α-naphthylglycocine on heating with sodium and amyl alcohol.

α-Naphthylglycocinenaphthylide, $C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}C_{10}H_7$, is prepared by heating α-naphthylglycocine with α-naphthylamine in molecular proportion in an oil-bath at 200°, removing the resinous bye-products by treatment with boiling ether, and crystallising the

residue from alcohol. It forms small needles, melts at 160°, is insoluble in cold ether, and gives α-dinaphthyl-αγ-diketopiperazine (*loc. cit.*) when treated with sodium ethoxide and ethyl chloracetate.

Ethyl β-naphthylidoacetate, prepared in the same way as the α-compound, melts at 88°, and gives β-naphthylglycocine when heated with alcoholic potash for 12 hours on the water-bath.

β-Dinaphthyl-αγ-diketopiperazine, when fused with potash, yields β-naphthylglycocine, and, when dissolved in glacial acetic acid and treated with potassium nitrite, it gives a compound, $C_{24}H_{18}N_2O_2$, melting above 360°.

Acetyl-β-naphthylglycocine, $C_{10}H_7{\cdot}NAc{\cdot}CH_2{\cdot}COOH$, is obtained by heating β-naphthylglycocine with acetic anhydride at 150°; it crystallises in needles, melts at 172°, and is readily soluble in alcohol, but only sparingly so in benzene. A. R. L.

Derivatives of α- and β-Naphthylidoisobutyric Acids, &c. By C. A. Bischoff and N. Mintz (*Ber.*, **25**, 2345—2354).—*Ethyl α-naphthyl-β-amidoisobutyrate*, $C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}CHMe{\cdot}COOEt$, is thus prepared:—Ethyl α-bromisobutyrate (100 grams), α-naphthylamine (73·3 grams), and anhydrous sodium carbonate (27·2 grams) are heated together at 175—200°, the solid product is extracted with ether, and the extract distilled; the portion passing over between 200° and 220° under a pressure of 15 mm. solidifies, and can be crystallised from alcohol, when it forms rhombic tables melting at 76·5°. The corresponding *acid* obtained on hydrolysing the salt with potash, and also by boiling a mixture of α-bromisobutyric acid (50 grams), α-naphthylamine (86 grams), and water (1 litre), crystallises from alcohol in six-sided tables, melts at 146°, and is almost insoluble in water; on distillation, α-naphthylamine and a *lactone*, melting at 107°, are isolated. The *acetyl* derivative,

$$C_{10}H_7{\cdot}NAc{\cdot}C_3H_6{\cdot}COOH,$$

melts at 246°.

Ethyl β-naphthyl-β-amidoisobutyrate, $C_{10}H_7{\cdot}NH{\cdot}CH_2{\cdot}CHMe{\cdot}COOEt$, prepared by heating a mixture of ethyl α-bromobutyrate (200 grams), β-naphthylamine (146 grams), and anhydrous sodium carbonate (54 grams) for five hours at 170°, is isolated from the portion of the product passing over at 215—235° (11 mm.), which solidifies and crystallises from alcohol in translucent truncated prisms, and melts at 58°. When the ethyl salt is hydrolysed in the usual manner, there is some difficulty in isolating the acid; this is best prepared in the same way as the acid derived from α-naphthylamine (see above) from α-bromisobutyric acid, β-naphthylamine, and water. It crystallises from alcohol in leaflets, melts at 188°, and is almost insoluble in water; it gives an *acetyl derivative*, $C_{10}H_7{\cdot}NAc{\cdot}C_3H_6{\cdot}COOH$, which melts at 188°, and is sparingly soluble in water.

β-Anilidopropionic acid (phenyl-β-alanine), $NHPh{\cdot}C_2H_4{\cdot}COOH$, is obtained when β-iodopropionic acid (20 grams), aniline (19 grams), and water (20 c.c.) are heated together in a reflux apparatus; after warming with dilute hydrochloric acid, the liquid is rendered alkaline, and a current of steam driven through the solution; on now

adding hydrochloric acid, an oil separates, which, when dissolved in ether, slowly deposits crystals. These, after recrystallisation from a mixture of chloroform and light petroleum, form lustrous leaflets which melt at 59—60°, and decompose with the evolution of aniline if heated above their melting point.

β-Paratoluidopropionic acid (*paratolyl-β-alanine*),

$$C_6H_4Me\cdot NH\cdot C_2H_4\cdot COOH,$$

melts at 86°. A. R. L.

The Camphor Group. By U. Alvisi (*Gazzetta*, **22**, i, 265—275).—An attempt made to prepare a cyanhydrin from camphor was unsuccessful, hydrogen cyanide having no action on camphor either at the ordinary temperature or at 60—80°, or even when in the nascent condition. The monobromocamphor, melting at 144°, prepared by Cazeneuve (Abstr., 1889, 1204) by the action of hypobromous acid on camphor could not be isolated, the product of the reaction after purification containing 6 to 11 per cent. of bromine. On boiling α-dibromocamphor with concentrated aqueous potash, it is in great part converted into the monobromocamphor melting at 76°. It further appears that in the conversion of α-dibromocamphor into monobromocamphor by heating it with potassium permanganate in alkaline solution, the action of the permanganate is quite secondary, being limited to the formation of some resinous and other bye-products.

On treating dibromocamphor (1 mol.) with phenylhydrazine (2 mols.), the product consists of the hydrazone, $N_2H_2Ph\cdot C_{10}H_{14}:N_2HPh$, monobromocamphor, ammonium bromide, aniline hydrobromide, phenylhydrazine hydrobromide, benzene, and nitrogen.

S. B. A. A.

Methyl Camphocarboxylates, Methylcamphor, and Azo-derivatives of Cyanocamphor. By J. Minguin (*Compt. rend.*, **115**, 120—122).—*Benzeneazocyanocamphor*, $C_8H_{14}<\begin{matrix}C(CN)\cdot N_2Ph\\ CO\end{matrix}$, is obtained by adding a solution of cyanocamphor in alcoholic potash gradually and with constant agitation to a solution of diazobenzene chloride cooled to 0°. It forms a yellow, viscous product, which afterwards solidifies, and crystallises from ether in small, yellow needles that melt with decomposition at 155°. It is only slightly soluble in ether, rather more soluble in alcohol, and very soluble in cold benzene.

Orthotolueneazocyanocamphor, $C_{10}H_{14}O\cdot(CN)\cdot N_2\cdot C_7H_7$, is obtained in a similar manner, and forms small, yellow needles, which melt with decomposition at 140°. It is more soluble in ether than its lower homologue, and is very soluble in cold benzene.

Paratolueneazocyanocamphor is obtained in a similar manner, and has similar properties. It melts at 137°, and in solubility is intermediate between the two preceding compounds.

When these derivatives are boiled with alcoholic potash for a few minutes, and the liquid is diluted and acidified with sulphuric acid,

a bulky precipitate separates. If it should at first be gelatinous, it is redissolved in sodium carbonate solution, and reprecipitated with sulphuric acid. When dried in a vacuum over sulphuric acid, they are all light, yellowish bodies, very soluble in cold ether, alcohol, and benzene, from which, however, they cannot be crystallised.

The azobenzene derivative has the empirical formula $C_{20}H_{25}O_3N_3$, and is a monobasic acid; its sodium salt separates from alcohol in yellowish, nacreous plates, and its silver salt rapidly becomes brown when exposed to light. C. H. B.

Alkylcyanocamphors and Alkyl Benzeneazocamphocarboxylates. By A. HALLER (*Compt. rend.*, **115**, 97—100).—Methyl methylcamphocarboxylate, when heated with hydrochloric acid, does not decompose even at 150°, but the cyanoalkylcamphors, in contact with hydrochloric acid, decompose to a considerable extent even in the cold, yielding cyanocamphor and alkyl chlorides. If the mixture is heated, camphocarboxylic acid is formed, and this in its turn yields camphor and carbonic anhydride.

Alcoholic solution of hydrogen chloride acts in the same way as the aqueous acid, and sulphuric acid acts even more rapidly than hydrochloric acid, the products being cyanocamphor and probably alkyl sulphates.

It seems necessary therefore to assume that the constitution of the alkyl cyanocamphors is represented by one of the following formulæ:—

$$(1.)\ C_8H_{14}\begin{cases}C{:}CNR\\ |\\ CO\end{cases}. \qquad (2.)\ C_8H_{14}\begin{cases}C{\cdot}CN\\ ||\\ C{\cdot}OR\end{cases}.$$

It would seem that cyanocamphor is tautomeric, and the radicle substituted for the hydrogen attaches itself to either the cyanogen group or the CO group, according to its nature.

Minguin has shown (preceding abstract) that the alkyl camphocarboxylates react with diazochlorides, and yield azo-derivatives.

Methyl benzeneazocamphocarboxylate, $\begin{matrix}C_8H_{14}\\ |\\ CO\end{matrix}\!>\!C\!<\!\begin{matrix}N_2{\cdot}C_6H_5\\ COOMe\end{matrix}$, is obtained by the action of diazobenzene chloride on methyl camphocarboxylate previously mixed with a solution of sodium in methyl alcohol. It separates as a viscous precipitate, which is dissolved in ether, and the ether is evaporated, when the residue gradually solidifies.

It crystallises from alcohol in beautiful, brilliant, yellow crystals, soluble in alcohol, ether, benzene, or toluene, less soluble in light petroleum, insoluble in alkalis. The crystals melt at 78°. When boiled with alcoholic potash, an acid is obtained which does not crystallise distinctly, and is very difficult to obtain pure. Hydrochloric and sulphuric acids yield yellow, uncrystallisable products.

Ethyl benzeneazocamphocarboxylate is obtained in a similar manner. It melts at 65·5°, and resembles the methyl salt in its general properties. C. H. B.

Action of Potassium Hypobromite on the Amide of Campholic Acid. By G. Errera (*Gazzetta*, **22**, i, 205—226).—*Campholic acid*, $C_9H_{17}\cdot COOH$, is best prepared by heating a solution of camphor (500 grams) in benzene (250 grams) in an iron cylinder to the boiling point, gradually adding metallic sodium (38 grams), distilling off the benzene at 180°, and heating the residual mass at 280° for 24 hours. The brown, viscous product is treated with hot water, shaken with ether, and the aqueous liquid acidified with hydrochloric acid and distilled. The yield is about 20 per cent. of pure acid. The *amide*, $C_9H_{17}\cdot CONH_2$, is prepared by heating the acid chloride with aqueous ammonia. It is separated from a small quantity of nitrile, which accompanies it, by distilling the mixture with water, the nitrile passing over with the steam. The amide crystallises from light petroleum in colourless, brilliant prisms, melts at 79—80°, dissolves readily in boiling water, separating from the solution, on cooling, in long, silky needles; it is freely soluble in alcohol and benzene. It strongly resists the action of bases, and is only converted into the acid with difficulty by prolonged boiling with potash. The change is readily effected, however, by heating it with dilute hydrochloric acid in a closed tube at 180°. On heating it with phosphoric anhydride, it yields the corresponding nitrile.

The *nitrile*, $C_9H_{17}\cdot CN$, is a colourless solid resembling camphor in appearance and odour, it melts at 72—73°, boils at 217—219°, and volatilises in a current of steam. It is insoluble in water, but very freely soluble in other solvents. It powerfully resists the action of bases, but is converted into campholic acid under the same conditions as the amide. When heated in alkaline solution at 40° with hydrogen peroxide, it is very partially converted into the amide. On reducing it with sodium in alcoholic solution, the corresponding amine, *campholamine*, $C_{10}H_{17}\cdot CH_2\cdot NH_2$, is obtained.

Campholyl isocyanate is prepared by dissolving campholamide in bromine (1 mol.), adding a 10 per cent. solution of potash until the liquid is decolorised, and repeatedly distilling in steam. It is a light, colourless liquid, which has the characteristic properties of the isocyanates, with the exception of the odour.

Bicampholylcarbamide, $CO(NH\cdot C_9H_{17})_2$.—This is the composition of the non-volatile residue, obtained in the preparation of the preceding compound; it may also be prepared by treating that substance with potash. It crystallises from alcohol in long, brilliant, flattened needles containing 1 mol. of alcohol, which they lose on exposure to the air, becoming dull and opaque. It melts at 220—221° and readily sublimes, boiling with decomposition at a slightly higher temperature. It is insoluble in water, but freely soluble in hot benzene. When heated in a closed tube at 150° with dilute hydrochloric acid, the product is a substance free from nitrogen. On heating it with water at 200°, the product probably consists of campholylamine.

Monocampholylcarbamide, $NH_2\cdot CO\cdot NH\cdot C_9H_{17}$, prepared by the action of ammonia on campholyl isocyanate, crystallises from water and light petroleum in long, thin needles, melts at 116—117°, and dissolves freely in alcohol and benzene, but only sparingly in cold water or light petroleum.

Campholylamine, $C_9H_{17}\cdot NH_2$.—On passing a current of hydrogen chloride through a mixture of campholyl isocyanate with a little light petroleum, a mass of crystals of an unstable additive compound separates; on adding water and gently heating, an energetic reaction takes place, the crystals disappear, and the liquid separates into two layers, of which the lower contains campholylamine hydrochloride. The free base is a colourless, waxy solid, resembling camphor in appearance, and having an ammoniacal and alliaceous odour; it boils at 174°, and has powerful basic properties. Its *hydrochloride* crystallises in large tabular prisms, very soluble in water. S. B. A. A.

Note.—The author applies the term "campholyl," to the radicle of the series containing 9 carbon atoms, next below and homologous with the campholic series.

Function of Camphoric Acid. By A. Haller (*Compt. rend.*, **114**, 1516—1520).—The action of hydrogen chloride on a solution of camphoric acid in methyl alcohol yields a mixture of methyl camphorates in proportions which vary with the conditions. *Methyl hydrogen camphorate* crystallises from a mixture of ether and light petroleum in large crystals, frequently lozenge-shaped, soluble in alcohol, benzene, toluene, and light petroleum, also in alkali hydroxides and carbonates. *Methyl camphorate* is a thick, oily liquid, which boils at 146—150° under a pressure of 10 mm., and at 175° under a pressure of 65 mm. It can also be prepared by heating in sealed tubes at 100° a mixture of methyl hydrogen camphorate, sodium methoxide, and methyl iodide. When treated with an equivalent quantity of alcoholic potash, it yields the potassium salt of the methyl hydrogen camphorate of saponification. The methyl hydrogen camphorate obtained by direct etherification seems to differ from that obtained by saponification. Their melting points and rotatory powers are as follows:—

	Melting point.	Specific rotatory power.
Methyl hydrogen camphorate of etherification	75—76°	$[\alpha]_D = +51{\cdot}52°$
Methyl hydrogen camphorate of saponification.....	85—86°	$[\alpha]_D = +43{\cdot}55°$
Methyl camphorate		$[\alpha]_D = +44{\cdot}40°$

All these ethereal salts on saponification yield camphoric acid.

When methyl hydrogen camphorate obtained by etherification is heated with phenylhydrazine in sealed tubes at 150—160°, it yields a compound which crystallises from a mixture of ether and light petroleum, and is purified by crystallisation; this melts at 119°, has a molecular rotatory power $[\alpha]_D = +16{\cdot}41°$, and has the composition of a pyrazolone corresponding with camphoric acid. It has, however, none of the properties of the pyrazolones, is insoluble in alkalis, and gives no coloration with ferric chloride. In function and constitution, it is analogous to the phthalylphenylhydrazine and succinylphenylhydrazine obtained by Hötte by the action of phthalic and succinic anhydrides respectively on phenylhydrazine. It would seem, therefore, that camphoric acid is dicarboxylic, and has the constitution $C_8H_{14}(COOH)_2$. This

view is supported by the fact that the compound in question can be obtained by the direct action of camphoric anhydride on phenylhydrazine (Friedel and Combes). Methyl camphorate has no action on phenylhydrazine at 100°, and, although there is an action at 150—160°, no definite products were isolated.

Methyl hydrogen camphorate, when gently heated with benzoic chloride, yields benzoic acid and camphoric anhydride, and in this respect behaves like camphoric acid. Methyl hydrogen camphorate, when dissolved in sodium hydroxide and treated with excess of benzoic chloride, yields a highly refractive liquid, which has the composition $C_{18}H_{22}O_4$, boils at 270—315° under a pressure of 80 mm., and is insoluble in alkalis. C. H. B.

Constitution of Camphoric Acid. By A. Haller (*Compt. rend.*, **115**, 19—21; compare preceding abstract).—When methyl hydrogen camphorate, obtained by etherification, is heated with a molecular proportion of phenylcarbimide at a temperature not exceeding 100°, it yields carbonic anhydride, diphenylcarbamide, and a product which dissolves in a mixture of ether and light petroleum, and crystallises in slender, white needles, soluble in alcohol, ether, benzene, and toluene, but insoluble in water or in alkalis. It melts at 78—79°, and its molecular rotatory power is $[\alpha]_D = +49° 20'$. It has the composition $C_{22}H_{34}O_7$, and its molecular weight, as determined by Raoult's method, in acetic acid solution, is 410. It seems, therefore, that no urethane is formed, and the phenylcarbimide acts simply as a dehydrating agent. It is noteworthy that methyl hydrogen phthalate and methyl hydrogen succinate, when heated with phenylcarbimide, yield phthalimide and succinimide respectively.

Methyl hydrogen camphorate, obtained by saponification (*loc. cit.*), when heated with phenylcarbimide under similar conditions, also yields a compound $C_{22}H_{34}O_7$, which crystallises from light petroleum in a radiated mass, and from alcohol in radiating groups of needles. It is soluble in ether and benzene, less soluble in light petroleum, insoluble in cold alkalis, melts at 62°, and has a molecular rotatory power $[\alpha]_D = +81° 27'$. The other products are carbonic anhydride and diphenylcarbamide, and it follows that the general nature of the reaction is the same as with methyl hydrogen camphorate obtained by etherification. It is impossible, therefore, to assume that the two isomerides have different functions. C. H. B.

Essential Oils. By Schimmel (*Zeit. anal. Chem.*, **31**, 357—358).—*Oil of Lavender.*—The true oil contains no camphor, and but traces of substances of low boiling point. Cineole, which occurs in considerable proportions in oil of *Lavandula spica*, is likewise absent from the true oil, the chief constituents of which are an alcohol, $C_{10}H_{18}O$, identical with Semmler's linaloöl (Abstr., 1891, 540), and its acetate. The alcohol boils at 197—199°, has a sp. gr. of 0·869 at 20°, and in a 100-mm. tube rotates the plane of polarised light through −10° 35'; the refractive index for D is 1·64. [In another part of the paper the sp. gr. of pure linaloöl is stated to be 0·878 at 15°, and its optical rotating power as +2°.] Heated with dehydrating agents, it

yields dipentene and terpinene, also other products. On oxidation, it yields geranaldehyde ("citral"), whose sp. gr. is 0·8972 (Abstr., 1891, 539, where it is misprinted 0·1972); refractive index 1·490. Geranaldehyde is converted by dehydrating agents into cymene. Linaloöl absorbs 4 atoms of bromine; with hydrogen chloride it yields a liquid of the composition $C_{10}H_{18}Cl_2$. Acid anhydrides produce the corresponding ethers, which are substances of agreeable odour. The acetate occurs to the extent of 40 per cent. in oil of bergamot, and has the characteristic odour of that oil.

Thoms' method of valuing oil of cloves (this vol., p. 250) affords results agreeing within 1 per cent. On the other hand, Panajotow's proposal for the detection of geranium oil in oil of rose, by means of a magenta solution decolorised by sulphurous acid, is useless.

M. J. S.

Isomerism in the Limonene Series. By O. Wallach (*Annalen*, **270**, 171—196).—*Benzoyllimonene nitrosochloride*, $C_{17}H_{20}NO_2Cl$, is slowly formed when α-limonene nitrosochloride is treated with benzoic chloride in ethereal solution at the ordinary temperature; it separates from ethyl acetate in rhombic crystals, and is only sparingly soluble in ether. This compound exists in two optically active modifications, corresponding with the two α-limonene nitrosochlorides; both forms melt at 109—110°, and have a specific rotatory power $[\alpha]_D = \pm 101{\cdot}8°$. When equal quantities of the dextrorotatory and lævorotatory compounds are dissolved in ethyl acetate, the inactive *dipentene* derivative is deposited in crystals on evaporating; this substance melts at 90°, and is much more readily soluble than the two active modifications.

β-Limonene nitrosochloride yields a benzoyl derivative, which is identical with that obtained from the α-compound.

Benzoylhydrochlorocarvoxime, $C_{17}H_{20}NO_2Cl$ (m. p. 114—115°), prepared from dextrorotatory hydrochlorocarvoxime, has a specific rotatory power $[\alpha]_D = -10{\cdot}58°$; the benzoyl derivative of the corresponding lævorotatory compound has a specific rotatory power $[\alpha]_D = 9{\cdot}92°$; it is evident, therefore, that these compounds are not identical, but isomeric with the benzoyl derivatives of the limonene nitrosochlorides.

The two limonenenitrolanilides prepared from α-limonene nitrosochloride are identical in properties with the corresponding compounds obtained from β-limonene nitrosochloride.

α-Limonenenitrolanilide forms monosymmetric crystals, melts at 112—113°, and exists in two modifications having specific rotatory powers $[\alpha]_D = \pm 101{\cdot}75°$ to $102{\cdot}62°$. The *nitroso*-derivative,

$$NO{\cdot}C_{10}H_{16}{\cdot}NPh{\cdot}NO,$$

prepared by treating α-limonenenenitrolanilide with sodium nitrite and acetic acid, separates from hot alcohol in colourless crystals, melts at 142°, and is soluble in about 10 parts of ether or benzene, but only sparingly in cold glacial acetic acid; it exists in two optically active modifications, $[\alpha]_D = \pm 46{\cdot}20°$ to $47{\cdot}82°$, corresponding with the two optically active α-nitrolanilides, and by combining equal quantities of the two substances *α-nitrosodipentenenenitrolanilide* is obtained in well-defined crystals, which melt at 147° with decomposition.

β-Limonenenitrolanilide crystallises in moss-like needles, melts at 153°, and is readily soluble in chloroform, alcohol, and hot benzene, but only sparingly in ether, and insoluble in light petroleum; its specific rotatory power is $[\alpha]_D = \pm 87{\cdot}17°$ to $89{\cdot}39°$. The *nitroso*-derivative separates from hot alcohol in yellowish prisms, and melts at 136° with decomposition; it exists in two optically active modifications which when combined form an inactive compound melting at 129°.

The above experiments seem to prove that α- and β-limonene nitrosochloride are chemically identical, but whether this is true or not in the case of the α- and β-nitrolanilides is an open question. In the first place, it has not yet been found possible to convert one nitrolanilide into the other; the basicity of the two compounds is widely different, the α-anilide being precipitated from its solution in acetic acid on the addition of water, whilst the β-compound remains in solution in the form of its acetate. Both compounds undergo decomposition on heating; the α-anilide yields aniline and carvoxime, whereas the β-compound gives aniline and a substance which has a distinct isonitrile-like odour. When dextrorotatory α-limonenenitrolanilide is treated with hydrogen chloride in methyl alcoholic solution and, after keeping for some days, the solvent is evaporated, a crystalline powder is left; this, after having been washed with ammonia and recrystallised from alcohol, melts at 115°, and is very similar to hydrochlorolimonenenitrolanilide (see below) in appearance. Both dextrorotatory and lævorotatory β-limonenenitrolanilide give under the same conditions a crystalline substance of the composition $C_{16}H_{23}ClN_2O$, which melts at 78°; the inactive dipentene derivative, obtained by combining these two active modifications (m. p. 78°), melts at 90°. The α- and β-nitrolanilides were proved to have the same molecular weight by determinations carried out by the boiling point method.

Hydrochlorolimonene does not combine with anhydrous hydrogen chloride; when kept for some time, it seems to undergo polymerisation and, at the same time, its rotatory power diminishes.

Hydrochlorolimonenenitrolbenzylamine, $NO{\cdot}C_{10}H_{17}Cl{\cdot}NH{\cdot}C_7H_7$, prepared by treating the dextrorotatory nitrosate with benzylamine in alcoholic solution, crystallises in moss-like needles, melts at 103—104°, and is very readily soluble in alcohol, ether, and benzene, but only sparingly in cold, light petroleum; its specific rotatory power is $[\alpha]_D = +149{\cdot}6°$. When treated with hydrogen chloride in ethereal solution, it yields a crystalline salt, which melts at 163—164°, and is dextrorotatory. The corresponding lævorotatory compound, prepared in like manner, has a specific rotatory power $[\alpha]_D = -147{\cdot}4°$.

Hydrochlorodipentenenitrolbenzylamine is invariably obtained as a bye-product in the preparation of the active isomerides; it is but sparingly soluble in all solvents, and melts at 150°.

Hydrochlorolimonenenitrolanilide, $NO{\cdot}C_{10}H_{17}Cl{\cdot}NHPh$, is formed, together with the corresponding dipentene derivative, when aniline is added to a warm benzene solution of the nitrosate; it separates from alcohol in crystals, melts at 117—118°, and is optically active in the same direction as the nitrosate from which it has been prepared.

The corresponding *dipentene* derivative melts at 139—141°, and is much more sparingly soluble in alcohol; when treated with alcoholic potash, it yields two bases, melting at 123—124° and 158° respectively, which closely resemble the α- and β-nitrolanilides of the dipentene series. F. S. K.

Constitution of Carvene. By A. Reychler (*Bull. Soc. Chim.* [3], **7**, 36—41).—A theoretical discussion as to the constitution of carvene and of limonene. T. G. N.

Action of Chlorine on Dihydrochlorodipentene. By O. Wallach and A. Hesse (*Annalen*, **270**, 196—203).—A *trichloride*, of the composition $C_{10}H_{17}Cl_3$, is formed, with evolution of hydrogen chloride, when well-dried chlorine is passed into a carbon bisulphide solution of dihydrochlorodipentene exposed to direct sunlight, until the colour, which first becomes green, has changed to yellow; it crystallises from alcohol in lustrous, colourless plates, melts at 87°, and boils at 145—150° under a pressure of 10 mm. The *tetrachloride*, $C_{10}H_{16}Cl_4$, is obtained when the treatment with chlorine is continued, under the conditions just described, for a long time; after purification by fractional distillation under reduced pressure, the product separates from ethyl acetate in well-defined symmetric crystals, melting at 108°.

When the trichloride is warmed for 6—7 hours with excess of sodium ethoxide in alcoholic solution, it yields a heavy oil, which still contains chlorine; when boiled for 5—6 hours with a glacial acetic acid solution of sodium acetate, it is converted into an oily *dichloride* of the composition $C_{10}H_{16}Cl_2$. This dichloride combines with hydrogen chloride in glacial acetic acid solution, yielding the original trichloride; when treated with bromine in glacial acetic acid solution, it yields a *dibromide* of the composition $C_{10}H_{16}Cl_2Br_2$, which, on recrystallisation from ethyl acetate, is deposited in transparent prisms melting at 98°.

The *nitrosochloride*, $C_{10}H_{16}Cl_2,NOCl$, prepared by treating the dichloride with amyl nitrite and hydrochloric acid in glacial acetic acid solution, is a crystalline powder melting at 111°. The *nitrolanilide*, $NO{\cdot}C_{10}H_{16}Cl_2{\cdot}NHPh$, crystallises in slender needles, and melts at 140—141°. The *nitrolpiperidide*, $NO{\cdot}C_{10}H_{16}Cl_2{\cdot}C_5NH_{10}$, crystallises from alcohol in lustrous plates, and melts at 147°. F. S. K.

Degree of Saturation of the Dextroterpene from Russian Turpentine. By A. Shtchoukareff (*J. Russ. Chem. Soc.*, **22**, 290—296).—The author has made an investigation on the number of atoms of bromine which a molecule of the right-handed terpene from Russian turpentine can directly take up. His first method was to dissolve a known quantity of the turpentine in chloroform (afterwards discarded for carbon tetrachloride), and add to this solution, in a stoppered flask, bromine solution of known strength (also in chloroform or carbon tetrachloride), until the colour ceased to disappear after 5 or 10 minutes. The contents of the flask were then shaken up with water, and the aqueous solution titrated with standard alkali,

to ascertain the quantity of hydrobromic acid formed, if any. The following table gives specimens of his results :—

Experiment.	I.	II.	III.
Bromine required by 1 mol. (136 parts) $C_{10}H_{16}$	169	151	172
Bromine converted into HBr	18	21	21

His second method was to add, at once, a large excess of bromine, allow the mixture to remain for a considerable time, titrate the unchanged bromine by means of potassium iodide and sodium thiosulphate, and titrate for hydrobromic acid with standard potash solution.

A considerably larger quantity of bromine disappeared under these conditions, as may be seen from the following table :—

Experiment.	I.	II.	III.
Bromine required by 1 mol. $C_{10}H_{16}$	307	317	309
Bromine converted into HBr	54	52	47

These last results confirm Tilden's observations on the pinenes, which take up more than 2 atoms of bromine per molecule. The author considers that the terpene examined, when treated with excess of bromine, combines with 4 atoms of the halogen to form an unstable compound $C_{10}H_{16}Br_4$, which decomposes in part into $C_{10}H_{15}Br_3$ and hydrogen bromide. This is analogous to the behaviour of the camphenes, which absorb 2 atoms of bromine, and then give off 1 mol. of hydrogen bromide. J. W.

Reduction of Hydrate of Terpinol. By A. Shtchoukareff (*J. Russ. Chem. Soc.*, **22**, 296—298). — Hydrate of terpinol, $C_{10}H_{20}O_2 + H_2O$, heated at 210° in a sealed tube with 1½ times the theoretical quantity of hydriodic acid of sp. gr. 1·7, and a little amorphous phosphorus, yields a large quantity of a hydrocarbon, $C_{10}H_{20}$. A portion of the crude reduction product is volatile with steam, boiling at 165—172°. This portion was treated with fuming sulphuric acid, washed, boiled some hours with metallic sodium, and fractionated; about half passed over between 168° and 170°. This is the hydrocarbon $C_{10}H_{20}$. Its sp. gr. at 15°/15° is 0·797. It is not attacked by sulphuric acid or by bromine at the ordinary temperature, and does not form a crystalline product with bromine in presence of aluminium bromide. It is probably identical with the hydrocarbon of the same composition obtained from menthol.

The portion not volatile with steam (more than half of the whole reduced product) boiled mostly between 310° and 315°. It is a viscous, fluorescent liquid. J. W.

Condurangin. By G. Carrara (*Gazzetta*, **22**, i, 236—242).—Condurangin is a glucoside, first obtained by Vulpius, from the bark of *Gonolobus condurango*, and considered by some writers as identical with vincetoxin from *Asclepias vincetoxicum*. It may be separated into two parts, one of which is soluble in water, the other insoluble. The best method of preparing it, is to extract the bark with 95 per cent. alcohol in a reflux apparatus, filter, distil off the greater part of the alcohol, take up with cold water, filter again, add concentrated solution of ammonium carbonate, and heat gently. The precipitate thus formed is washed with hot water, redissolved in cold water, containing, if necessary, a few drops of alcohol, basic lead acetate added, the precipitate thoroughly washed, suspended in water, and decomposed with hydrogen sulphide; the brown solution obtained is then precipitated with a concentrated solution of common salt. The precipitate, after purification, consists of a mixture of the two modifications of condurangin. Insoluble condurangin is precipitated from a benzene solution on the addition of excess of light petroleum, as a light, almost white powder, which melts at 60—61°, and has the percentage composition $C_{20}H_{32}O_6$. Its molecular weight, as determined by the cryoscopic method, agrees with this formula.

Soluble condurangin, obtained by the evaporation of an aqueous extract of the mixed varieties, is a yellowish substance melting at 134°. It appears to have the composition $C_{18}H_{28}O_7$, but its molecular weight could not be determined. On boiling either of these compounds with acids, the principal product is a brown, pitchy substance, insoluble in water. With Fröhde's reagent, an aqueous solution of the soluble condurangin yields a greenish coloration, and after a time a flocculent, green precipitate, the insoluble variety, suspended in water, gives no reaction, or only a yellowish coloration.

S. B. A. A.

Santonic Acid. By L. Francesconi (*Gazzetta*, **22**, i, 181—205).—*Santonic acid*, $C_{15}H_{20}O_4$, was first obtained by Cannizzaro by the action of baryta on santonin, and many of its properties have already been described.

The *oxime* of ethyl santonate, $COOEt{\cdot}C_{12}H_{17}O{<}\begin{matrix}CH_2\\|\\C{:}NOH\end{matrix}$, crystallises from alcohol in tufts of white laminæ, melts at 126—127°, dissolves readily in ether and alcohol, but only very sparingly in water. It is lævorotatory, $[\alpha]_D = -36{\cdot}5$. On treating it with dilute hydrochloric acid, it splits up into ethyl santonate and hydroxylamine. In the preparation of this compound, a small quantity of a secondary product is formed, having approximately the composition of the oxime of santonic acid. It crystallises, however, from alcohol in long needles, melting at 189·5°, and is only very sparingly soluble in ether, and almost insoluble in water. It also forms a barium salt, more soluble than that of the acid oxime.

The *oxime* of santonic acid, $COOH{\cdot}C_{12}H_{17}O{<}\begin{matrix}CH_2\\|\\C{:}NOH\end{matrix}$, is best prepared by heating an alcoholic solution of santonic acid and hydroxylamine hydrochloride with precipitated calcium carbonate. When

pure, it forms small crystals melting at 186—187°, and moderately soluble in ether, alcohol, and hot water. It is lævorotatory, $[\alpha]_D = -64{\cdot}9$. Dilute hydrochloric acid decomposes it into santonic acid and hydroxylamine.

The *amine* of ethyl santonate, $COOEt{\cdot}C_{12}H_{17}O{<}\begin{matrix}CH_2\\|\\CH{\cdot}NH_2\end{matrix}$, obtained by reducing a solution of the oxime in alcohol and acetic acid with sodium amalgam, crystallises from ether in hexagonal tables, and melts at 130—141°. It dissolves very sparingly in water, forming a strongly alkaline solution, and is moderately soluble in ether and alcohol. It turns yellow if heated for some time at 100°; its alcoholic solution likewise undergoes alteration on heating. It is dextrorotatory, $[\alpha]_D = +131{\cdot}34$.

Hyposantonic acid, $C_{15}H_{20}O_3$, is prepared by heating an acetic acid solution of the preceding amine with sodium nitrite. The pure acid obtained from the barium salt, crystallises from ether in microscopic needles, and melts at 135—136°.

The *hydrazone* of ethyl santonate, $COOEt{\cdot}C_{12}H_{17}O{<}\begin{matrix}CH_2\\|\\C{\cdot}N_2HPh\end{matrix}$, crystallises from alcohol in clear, yellow plates, and melts at 115—116°. It is moderately soluble in cold ether and alcohol, but only very sparingly in cold water; it is decomposed by hot water, and readily altered by exposure to sunlight. Its alcoholic solution is blackened by hydrochloric acid. On reducing it with sodium amalgam, only traces of the amine are formed.

On oxidising santonic acid with potassium permanganate, concentrating the clear solution in a vacuum, acidifying with sulphuric acid, repeatedly extracting with much ether, and evaporating the ethereal solution, a viscous residue is obtained, from which, by recrystallisation from a mixture of ether and chloroform, a white solid, melting at 176°, can be separated. This substance is a tetrabasic acid, having the composition $C_{13}H_{18}O_8$; it is very soluble in water, forming a strongly acid solution; it is moderately soluble in ether and alcohol, and insoluble in chloroform; it dissolves in solutions of alkali carbonates with evolution of carbonic anhydride. It is dextrorotatory, $[\alpha]_D = +28{\cdot}56$. The *silver* salt, $C_{13}H_{14}Ag_4O_8$, forms white flakes.

On heating the acid at its melting point, or, preferably, at 180—181°, it loses 1 mol. H_2O, and the *monanhydride*, $C_{13}H_{16}O_7$, is left; this crystallises from dry ether in white, shining prisms, and melts at 192—193°; it dissolves in absolute alcohol, forming a feebly acid solution. On heating the acid or the monanhydride with acetic anhydride for four hours, distilling off the excess of that reagent and adding excess of dry ether, the *dianhydride*, $C_{13}H_{14}O_6$, is precipitated as a white, crystalline powder, consisting of minute plates or tufts of needles. It melts at 151—152°, and is soluble in acetic anhydride or in hot water, but not in ether. On concentrating the aqueous solution of either of these anhydrides, a viscous mass is left, but no crystals are deposited; when this is dried over sulphuric acid in a vacuum, or heated for some hours at 100°, the product is an acid,

strongly resembling the acid obtained by the oxidation of santonic acid, but differing from it in not crystallising from water or ether, in its greater solubility in a mixture of ether and chloroform, and in losing 1 mol. H_2O at 135—145°. When the oxidation acid is dissolved in acetic anhydride at a gentle heat, and dry ether is immediately added, a deposit of long, colourless needles is formed, consisting of a dianhydride, melting at 134—135°. This is converted into the dianhydride, melting at 151—152°, by heating it at its melting point, and its aqueous solution, on concentration, readily yields the acid melting at 176°, together with small quantities of its isomeride.

S. B. A. A.

Chrysophanic Acid. By V. Grandis (*Chem. Centr.*, 1892, i, 592—593; from *Ann. Chim. Farm.*, **15**, 1—9).—The author has prepared chrysophanic acid from chrysarobin according to the directions given by Liebermann, and finds the melting point to lie between 162° and 187°, although the product was repeatedly crystallised from benzene. The sublimed substance melted at 185—187°, and this melting point was further raised to 190—191° by recrystallisation. In all other respects the specimen appeared to be identical with that described by Liebermann. The results of the elementary analysis agreed with the formula $C_{15}H_{10}O_4$, and the diacetyl and dibenzoyl derivatives likewise possessed the melting points and physical characters of the corresponding compounds described by him. J. W. L.

Euxanthic Acid and Euxanthone. By J. Herzig (*Monatsh.*, **13**, 411—421).—In a previous paper, the author has shown that a similiarity exists between euxanthone and quercetin, inasmuch as both yield yellow alkyl derivatives which are insoluble in alkali, and yield colourless compounds on acetylation (Abstr., 1891, 1349). Euxanthic acid on acetylation is also converted into a colourless *tetracetyl* derivative, $C_{13}H_6(OAc)_4O$, which crystallises from alcohol in white plates, and melts at 118—119° (uncorr.). The hydrolysis with sulphuric acid does not proceed so smoothly as with the acetyl derivatives of quercetin and euxanthone, the euxanthic acid being mostly converted into euxanthone by further loss of water, and the filtrate has always a yellow colour.

On alkylation, euxanthic acid no longer behaves in a similar manner to euxanthone, as only the tetrethyl ether, $C_{13}H_6O(OEt)_4$, could be isolated, although small quantities of a yellow substance are formed which may possibly be a lower ether. The tetrethyl ether is sparingly soluble in alcohol, and crystallises from the solution in white plates or flat needles melting at 93—95°. Fisetin, which is closely related to quercetin, resembles euxanthic acid in only yielding the completely ethylated compound.

The tetrethyl ether corresponds with euxanthone in its behaviour towards potash, as it is not attacked by the alcoholic solution at 100°, and even at 150° it is not converted into a phenol and a hydroxy-acid; in this respect, therefore, the euxanthone derivatives differ from those of quercetin, as the latter are readily resolved by potash.

Although euxanthone and xanthone do not combine with hydroxyl-

amine, euxanthic acid readily unites with both. In the case of hydroxylamine, however, the product has the composition $C_{13}H_9NO_4$, the elements of water having been eliminated and a derivative of euxanthone apparently formed; it crystallises in white needles and melts at 233—235°, previously becoming slightly brown. The phenylhydrazone has not been obtained pure.

The following results have also been obtained with regard to the monethyleuxanthones previously described (*loc. cit.*). Both can be obtained from euxanthone and reconverted into it, so that they are true derivatives. The white modification yields an acetyl derivative which crystallises from alcohol in white needles and melts at 164—166°. Neither modification combines with phenylhydrazine.

H. G. C.

Chlorophyll. By N. Monteverde (*Ann. Agron.*, **18**, 268—270).—The author discusses the question of how many different pigments are contained in an alcoholic solution of chlorophyll. If, after Frémy, the alcoholic extract of leaves of wheat be treated with baryta water, and the precipitate exhausted with alcohol, a yellow solution is obtained; on adding some drops of water and shaking with light petroleum, the yellow is separated, and can be purified by agitation with fresh portions of alcohol or light petroleum, the latter dissolving carotin, and the former xanthophyll. The solution of carotin agrees exactly, optically and chemically, with that of crystallisable carotin extracted from carrots or dead leaves; its spectrum shows three absorption bands between F and H. The crystals of xanthophyll are distinguished from those of carotin by their form, colour, and by microchemical reactions, as to which the author entirely confirms Borodin. Whilst hydrochloric acid precipitates carotin from its alcoholic solution without alteration, it decomposes xanthophyll, giving rise to a blue substance, and the three absorption bands between F and H are replaced by continuous absorption at that end of the spectrum. Etiolated leaves of wheat contain only very small quantities of carotin, but after a short daily exposure to light crystallisable carotin can be obtained from them. The author has found these two colouring matters in the yellow autumnal leaves of many ligneous plants. He has extracted from the leaves of *Scrophularia nodosa* a third pigment, agreeing with the "golden yellow," of Borodin. The young leaves of *Potamogeton natans* are yellow-brown, the colour cells containing, in addition to the yellow and green pigments, a red one which disappears later on. This substance is not crystallisable, is insoluble in water, but dissolves easily in alcohol to a cherry-red.

When an alcoholic solution of chlorophyll is shaken with benzene or light petroleum, the upper layer contains both green colouring matter and carotin. If this is decanted, mixed with a large quantity of absolute alcohol, and water added drop by drop, a point can be hit at which all the green colouring matter is transferred to the alcohol, the other solvent retaining the carotin. (The slightest excess of water causes all the green pigment to leave the alcohol.) By repeating this process several times, each time decanting off the solution of carotin, the author obtains a purified green pigment, which gives

only the first four absorption bands and a continuous absorption in the extreme violet. The cyanophyll spectrum of Kraus is, therefore, a combined spectrum of the pure green pigment and carotin. The pure green pigment does not crystallise. Heated with hydrochloric acid, it yields pure brown-yellow chlorophyllane with absorption bands I, IV*a*, IV*b*, II, III, and an absorption in the extreme violet; flocks of pure phyllocyanin are also formed.

The alcoholic extract of certain plants does not behave as above described; the benzene or light petroleum may take only the carotin, leaving the green pigment and xanthophyll in the alcohol. In this case the author speaks of an "inferior green pigment," yielding with hydrochloric acid "inferior chlorophyllane" and "inferior phyllocyanin." This inferior green pigment crystallises in tetrahedra, hexagonal plates, and stars, but oftenest in a very irregular manner. The pure crystals, appearing to the eye as a dark-brown, almost black, powder, are identical with the chlorophyll crystals which Borodin obtained by moistening microscopic sections with alcohol and allowing them to dry. They are easily soluble in alcohol, insoluble in light petroleum, carbon bisulphide, and commercial benzene, but soluble in pure benzene (this explains the contradiction between Tschirch and Borodin). The alcoholic solution is fluorescent; its spectrum has absorption bands I to IV, and possibly bands between F and H. The band IV*b* is entirely absent, from which one must conclude that chlorophyllane is not present, as Tschirch believed.

The author concludes that living leaves contain only the inferior green pigment. Treatment of the leaves with boiling water, however, nearly always transforms the inferior green into the superior. This transformation can only be effected in the leaves themselves, for the crystals of inferior green pigment do not yield the superior when boiled in alcoholic solution. J. M. H. M.

Chloriodides of Organic Bases. By A. Pictet and G. Krafft (*Bull. Soc. Chim.* [3], **7**, 72—75).—When a mixture of iodine trichloride with pyridine, piperidine, quinoline, or trimethylamine, in molecular proportion, is heated with water and the solution concentrated, an abundant crystallisation of yellow needles of the chloriodide of the base is obtained according to the equations:—

$$2ICl_3 + 3H_2O = ICl + 5HCl + HIO_3,$$
$$C_5H_5N + ICl + HCl = C_5H_5N,ICl,HCl,$$

and these salts are identical with those obtained by Ostermayer and by Dittmar (Abstr., 1886, 158).

On treating these salts with sodium hydroxide, the white chloriodides are obtained which are insoluble in water but crystallise from ether in fine needles. They are strongly basic, the primitive salt being regenerated on treating them with hydrochloric acid. The hydrochloride yields double salts with platinum, gold, and mercury chlorides, and the chloriodide also forms crystalline salts with sulphuric, nitric, chromic, and picric acids.

Pyridine chloriodide, C_5H_6N,ICl.—White needles, melting at 132°.

The hydrochloride, C_5H_5N,ICl,HCl, melts at 180° and crystallises from water in long, yellow needles.

Quinoline chloriodide, C_9H_7N,ICl.—Small, white needles, melting at 159·5°. The hydrochloride, C_9H_7N,ICl,HCl, melting at 118°, is Osterwald's quinoiodine.

Piperidine chloriodide, $C_5H_{11}N,ICl$.—Fine, white needles, melting at 143°. The hydrochloride, $C_5H_{11}N,ICl,HCl$, forms yellow crystals and melts at 90°.

Trimethylamine chloriodide, NMe_3,ICl.—White needles, melting at 77°. The hydrochloride, NMe_3,ICl,HCl, forms yellow, tabular crystals and melts at 159°. The formation of this salt proves Dittmar's assertion, that the chloriodides are peculiar to the pyridine derivatives, to be incorrect. The authors consider that in the molecule of these chloriodides the nitrogen is pentavalent and is linked to each of the halogen atoms. T. G. N.

Pyridine-like Bases in Petroleum. By R. Zaloziecki (*Monatsh.*, **13**, 498—503).—These were obtained from the petroleum of Boryslav by diluting the acid which had been used to wash the oil, removing the tarry matter thus set free, adding quicklime in excess to the acid liquid, and distilling the bases thus liberated with steam. A mixture of bases was obtained, which exhibited many properties of the pyridine compounds. With platinum tetrachloride, one crystalline substance was obtained, which was probably the platosochloride of a hydrogenised pyridine, such as dihydrocoridine, $(C_5NMe_5H_2Cl)_2,PtCl_2$. The pyridine compounds are products of decomposition of the animal body, and their occurrence in petroleum is important as bearing on the formation of the latter. C. F. B.

Pyridinecarboxylic Acids obtained from Berberine. By R. Mayer (*Monatsh.*, **13**, 344—356).—The author has prepared berberonic acid (pyridinetricarboxylic acid) by the oxidation of commercial berberine (200 grams) with nitric acid, and finds that it melts at 234—235°, some 12 degrees lower than is given by Fürth (*Monatsh.*, **2**, 426). On boiling with a mixture of acetic acid and anhydride for six hours, it is converted, with loss of carbonic anhydride, into beronic acid. The latter agrees in all its properties, except that it melts at 249° instead of 263°, with the compound described by Fürth; and is shown by the crystalline form of its hydrochloride to be identical with cinchomeronic acid ($\beta\gamma$-pyridinedicarboxylic acid). The position of the third carboxyl group in berberonic acid must be either the α- or α_1-, since, with ferrous sulphate, it gives the characteristic blood-red coloration of substances so constituted. $\alpha\beta\gamma$-pyridinecarboxylic acid is known and is not identical with it, so that berberonic acid must be the $\alpha_1\beta\gamma$-compound.

The bye-product, of a yellow colour, obtained by Weidel (*Ber.*, **12**, 1148) during the oxidation of berberine by nitric acid, and thought by him to be a nitro-compound, proves to be merely impure cinchomeronic acid. G. T. M.

Derivatives of 2-Methyl-5-ethylpyridylalkine, $C_9H_{13}NO$. By G. Prausnitz (*Ber.*, **25**, 2394—2397).—*Ethylvinylpyridine*, $C_5NH_4Et{\cdot}CH{:}CH_2$, is obtained by heating methylethylpyridylalkine with 3—4 parts of concentrated hydrochloric acid in a sealed tube at 160—170° for 4—5 hours. The product is saturated with sodium hydroxide and distilled with steam. An oil is obtained which is extracted by shaking with ether, and the ethereal solution dried with potassium carbonate and evaporated. It boils at 98—102° under a pressure of 21 mm., is colourless, has an unpleasant odour, and is very easily soluble in ether, alcohol, and chloroform, sparingly so in water. The same compound is obtained by distilling the alkine over solid potassium hydroxide. The *aurochloride* is an oil. The *platinochloride* is not characteristic. The *double salt* with *mercuric chloride*, $(C_9H_{11}N.HCl)_2,5HgCl_2$, crystallises in beautiful needles, and is insoluble in cold water, sparingly soluble in hot water.

2-Methyl-5-ethylpiperidylalkine, $C_5NH_9Et{\cdot}CH_2{\cdot}CH_2{\cdot}OH$, is obtained by gradually adding alcohol (300 grams) to a mixture of metallic sodium (40 grams) and methylethylpyridylalkine (10 grams) dissolved in alcohol. The product is mixed with concentrated hydrochloric acid, the sodium chloride separated, and the filtrate evaporated to dryness and extracted with absolute alcohol. The solution is evaporated to a syrup, mixed with chloroform and concentrated sodium hydroxide, well shaken, and the chloroform extract dried over potassium carbonate and distilled under diminished pressure. First, a compound of the formula $C_{17}H_{35}N_3$ distils over at 105—110° under a pressure of 18 mm.; then methylethylpiperidylalkine distils at 170—180°; this is a viscid, colourless liquid, of strongly alkaline reaction, and is easily soluble in chloroform, less so in alcohol and ether. When treated with sodium nitrite, it yields an oily nitrosamine.

Diethylpiperidine, $C_5NH_9Et_2$, is obtained by reducing the alkine by Ladenburg's or Bamberger's method. After decomposing, by water, the sodium ethoxide which is formed, the alcohol is distilled off, and the residue extracted with ether. The ether is then distilled off, and the residue distilled with steam. The distillate thus obtained is acidified with hydrochloric acid, evaporated to a syrup, and allowed to crystallise over sulphuric acid in a vacuum. The hydrochloride thus obtained rapidly deliquesces on exposure to air. The *base* is obtained by decomposing the hydrochloride with solid potassium hydroxide; it boils at 100—105° under a pressure of 22 mm., and at 190° under the ordinary pressure. It is a colourless, limpid liquid, has a nauseous odour, reacts strongly alkaline to litmus, is very easily soluble in chloroform and ether, and yields an oily nitrosamine. Its sp. gr. = 0·8722 at 0°. E. C. R.

Quaternary Ammonium Bases of the Quinoline Series. By A. Claus (*J. pr. Chem.* [2], **46**, 106—128).—It has been shown (Abstr., 1891, 1252; this vol., p. 876) that two classes of bases are obtainable by the action of potassium hydroxide and of moist silver oxide on the halogen alkyl compounds of substituted quinolines. Those of the one kind are soluble in ether and include the bases prepared by acting with alkalis or moist silver oxide on the alkyl halogen

compounds of quinoline, of halogenised or nitrated quinolines, and, in certain cases (*loc. cit.*), of hydroxyquinolines; the author maintains that these bases are alkylene quinolines. Those of the other kind are insoluble in ether, and result, in most cases, from the action of alkalis or moist silver oxide on halogen alkyl compounds of hydroxyquinolines; these are quaternary ammonium bases. Experiments are quoted to show that Decker's nitrobromoquinolinemethylium hydroxide (this vol., p. 880) is not itself a base soluble in ether, but is converted into one by the combined action of the alkali and ether.

The bases insoluble in ether do not undergo oxidation when exposed to air or to the action of potassium ferricyanide, whereas the bases soluble in ether are oxidised under these circumstances without exception. In close connection with this observation, some experiments on the electrolysis of 3-hydroxyquinoline methosulphate and 4′-bromoquinoline methosulphate are touched on; details of this work will shortly be published. Some remarks on Decker's bases from acridine and phenylacridine (*loc. cit.*) conclude the paper.

Methylhydroxytoluquinoxaline and the Constitution of the Compounds obtained from α-Hydroxy-acids and Orthodiamines. By O. Hinsberg (*Ber.*, **25**, 2416—2421).—Autenrieth and Hinsberg (this vol., p. 709) came to the conclusion that no quinoxaline derivative is formed from orthotoluylenediamine and mandelic acid. Georgescu (this vol., p. 886), however, states that derivatives of tetraketoquinoxaline are obtained by the action of orthodiamines on mandelic acid and other α-hydroxy-acids. The author has arrived at the constitution of the compounds in the following way. Georgescu obtained a compound, to which he gave the formula

$$C_7H_6<\begin{matrix}NH\cdot CHMe\\ |\\ NH\cdot CO\end{matrix},$$

by the action of lactic acid on orthotoluylenediamine at 130°. A compound of this constitution should be obtained by reducing the nitro-compound $NO_2\cdot C_7H_6\cdot NH\cdot CHMe\cdot COOH$, and also by the action of ethyl α-bromopropionate on orthotoluylenediamine. By these methods the author has obtained a quinoxaline derivative of the above constitution which has quite different properties from those of Georgescu's compound.

Nitrotolualanine, $NO_2\cdot C_7H_6\cdot NH\cdot CHMe\cdot COOH$, is obtained by heating nitrotoluidine (2 mols.) with bromopropionic acid (1 mol.) for some hours at 115—120°. The product is warmed with dilute sodium hydroxide, and the yellow solution filtered and freed from nitrotoluidine by shaking with ether. On adding excess of hydrochloric acid to the alkaline liquid thus obtained, the nitrotolualanine is precipitated as an oil which soon solidifies. It crystallises from dilute alcohol in leaflets, melts at 148°, is sparingly soluble in water, easily so in ether and alcohol, and yields intensely reddish-yellow solutions.

Metamethyl-α-oxy-β-methylhydroquinoxaline, $C_6H_3<\begin{matrix}NH\cdot CHMe\\ |\\ NH\cdot CO\end{matrix}$, is

obtained by reducing the preceding nitro-compound with tin and hydrochloric acid. The greater part of the reduction product crystallises out as stannochloride; this is dissolved in hot water and alcohol, decomposed with excess of ammonia, and the precipitated hydroxymethyltoluquinoxaline purified by crystallisation from dilute alcohol. It is thus obtained in white leaflets, melts at 157°, is sparingly soluble in cold water, easily so in alcohol and ether. It is slightly decomposed on exposure to air, yields colourless solutions with dilute mineral acids, and dissolves in warm potassium and sodium hydroxides. When treated with sodium nitrite, in dilute acid solution, the *nitrosamine* is obtained in voluminous, slender, white needles which dissolve in alkalis with a yellowish-red colour. When oxidised with iodine and soda solution, or with silver nitrate and ammonia, it is easily converted into methylhydroxytoluquinoxaline which melts at 237°.

Hydromethyloxytoluquinoxaline is also obtained by heating pure toluylenediamine (3 mols.) and ethyl bromopropionate (2 mols.) for half an hour on the water bath in a current of carbonic anhydride. The product is dissolved in water, extracted with ether, the ethereal solution evaporated to dryness, and the residue crystallised first from water and then from dilute alcohol. The product obtained melted at 148—151°, but otherwise had the same properties as that obtained by the first method. The author believes that the impurity in this preparation is paramethyl-α-oxy-β-methylhydroquinoxaline.

E. C. R.

Action of Benzaldehyde on 2 : 6-Lutidine. By F. Schuster (*Ber.*, **25**, 2398—2405).—Benzylidene-2 : 6-lutidine and dibenzylidene-2 : 6-lutidine are obtained by the action of benzaldehyde on 2 : 6-lutidine. A mixture of benzaldehyde with 2 : 6-lutidine is heated with zinc chloride in a sealed tube at 225° for six hours; the product, a white, crystalline mass mixed with a small quantity of brown resin, is easily purified by drying on porous plates. The two bases thus obtained are separated by means of their hydrochlorides, benzylidene-2 : 6-lutidine hydrochloride being easily soluble in water, whilst the hydrochloride of the dibenzylidene base is very sparingly soluble. The hydrochlorides are easily decomposed by potassium hydroxide, the latter salt more easily on heating; a large excess of alkali is to be avoided, as the bases are somewhat soluble in alkali. The author was unable to obtain an intermediate compound of the aldol series by heating the components without the addition of zinc chloride; the monobenzylidene base cannot be obtained alone, but is always produced together with the dibenzylidene base.

Benzylidene-2 : 6-*lutidine*, $C_5NH_3Me{\cdot}CH{:}CHPh$, crystallises out in beautiful, nacreous plates when water is added to the alcoholic solution until a slight turbidity is produced. It melts at 123°, has a faint, characteristic odour, is easily soluble in ether, alcohol, benzene, chloroform, and carbon bisulphide, is volatile with difficulty in a current of steam, and is neutral to litmus. The *hydrochloride* crystallises in very slender, pale-yellow needles, and melts at 50°; when recrystallised from hydrochloric acid, it forms beautiful, bright-yellow crystals which contain 1 mol. H_2O. The anhydrous salt is

colourless, turns brown at 200°, and melts at 221° with decomposition. The *chromate* crystallises in yellowish-red needles, is easily soluble in boiling water, sparingly so in the cold, and turns brown at 280° without melting. The *mercurochloride*, $C_{14}NH_{13},HHgCl_3$, crystallises in interlacing needles, melts at 185°, and is sparingly soluble in cold water, but easily in alcohol and boiling water. The *platinochloride* crystallises in reddish-yellow, sparingly soluble needles, and blackens at 270°, but does not melt. The *aurochloride* crystallises in brick-red needles, melts at 211°, and is sparingly soluble in alcohol, almost insoluble in boiling water. The *picrate* crystallises in golden spangles, coagulates, blackens on heating, and melts at 217—219° with decomposition. The base also yields a sparingly soluble double salt with potassium ferrocyanide. The *hydrobromide* and *iodide* crystallise in sparingly soluble needles.

A *dibromide* of the formula $C_5NH_3Me{\cdot}CHBr{\cdot}CHBrPh$ is obtained by adding the requisite quantity of bromine to the base dissolved in carbon bisulphide. It crystallises in needles, and melts at 156° with decomposition.

When benzylidene-2 : 6-lutidine is reduced by boiling with sodium and absolute alcohol, a compound of the formula

$$C_5NH_3Me{\cdot}CH_2{\cdot}CH_2Ph$$

is obtained: this can be extracted from the product by ether, and crystallises from alcohol in leaflets. It melts at 80—81°, can be distilled with steam, is insoluble in water, easily soluble in ether, alcohol, benzene, and chloroform; has a strongly alkaline reaction when moistened with water, and has a faint characteristic odour. The *hydrochloride* forms colourless, fern-like crystals, and melts at 141°. The *platinochloride* crystallises in microscopic needles, and melts at 197° with decomposition. The *aurochloride* crystallises in beautiful, long, yellow needles, melts at 166°, and is somewhat easily soluble in alcohol. The *mercurochloride*, $C_{14}NH_{21},HHgCl_3$, is obtained in extremely slender needles, crystallises from alcohol in small leaflets, and melts at 138°.

Dibenzylidene-2 : 6-lutidine, $C_5NH_3(CH{:}CHPh)_2$, crystallises in beautiful, long, lustrous needles, melts at 167·5°, has no odour, is without action on litmus, and is insoluble in water, but soluble in alcohol, ether, benzene, chloroform, and carbon bisulphide. With hydrochloric acid, it yields an intensely yellow salt, which becomes colourless on drying. The *mercurochloride*, $C_{21}NH_{17},HHgCl_3$, crystallises in yellow needles, melts at 193°, and is insoluble in boiling water, easily soluble in warm alcohol. The *aurochloride* and *platinochloride* crystallise in small needles, and do not melt at 270°. The *picrate* crystallises in slender, yellow needles, turns brown and sinters at 150—160°, and melts at 220°. The *brominated* derivative, $C_5NH_3(CHBr{\cdot}CHBrPh)_2$, crystallises from absolute alcohol in interlacing needles, and melts at 183°.

Tetrahydrodibenzylidene-2 : 6-lutidine, $C_{21}H_{21}N$, is obtained by heating dibenzylidenelutidine (3 grams) with fuming hydriodic acid (30 grams) in a sealed tube for two hours at 160°. The product is treated with sulphurous acid, alkali added, and the base extracted

with ether. It crystallises from alcohol in colourless needles, melts at 153°, and is insoluble in water, but easily soluble in alcohol, benzene, ether, and chloroform. The *hydrochloride* crystallises in yellowish needles. The *platinochloride*, $(C_{21}NH_{21})_2,H_2PtCl_6 + H_2O$, crystallises in yellow needles, melts at 79—80°, and is soluble in hot water. The *picrate* crystallises in small needles, and melts at 149°. The *aurochloride* is an oil. E. C. R.

Diethyl Hydrofurfuryllutidinedicarboxylate and its Derivatives. By F. Heiber (*Ber.*, **25**, 2405—2407).—Diethyl hydrofurfuryllutidinedicarboxylate, $N\begin{matrix}\diagup CMe-\!\!-\!\!-\!\!-C(COOEt) \\ \diagdown CH(C_4H_3O)\cdot CH(COOEt)\end{matrix}\diagup CMe$, is obtained by warming a mixture of ethyl acetoacetate (2 mols.) and furfuraldehyde (1 mol.) with a slight excess of concentrated alcoholic ammonia for a few minutes at 40° with constant shaking. It melts at 163·5—164·5°.

Diethyl furfuryllutidinedicarboxylate nitrate, $C_{17}H_{19}NO_5,HNO_3$, is obtained by suspending the ethereal salt in three times the quantity of alcohol and passing nitrous acid into the mixture until a sample dissolves to a clear solution in hydrochloric acid. The product crystallises from dilute alcohol, melts at 118·5—119° with decomposition, and is very sparingly soluble in water, but easily in alcohol or ether. The mother liquors contain small quantities of the free base, which may be converted into nitrate by the careful addition of dilute nitric acid.

Diethyl furfuryllutidinedicarboxylate, $C_{17}H_{19}NO_5$, is obtained by shaking the above nitrate with sodium carbonate. It melts at 40—41°, becomes yellow on exposure to light, is insoluble in water, easily soluble in alcohol and ether, and cannot be obtained crystalline from the latter solvent. The *platinochloride* is obtained as a crystalline precipitate of the composition $(C_{17}H_{19}NO_5)_2,H_2PtCl_6$.

E. C. R.

Sparteïne. By A. Peratoner (*Gazzetta*, **22**, 566—571).—On heating sparteïne (2 grams) with water (30 c.c.) and silver oxide (10 grams) in a closed tube at 170—180° for 4—6 hours, metallic silver and much carbonic anhydride are obtained. On dissolving the product in water, filtering, treating with excess of potash, and distilling from an oil-bath, an aqueous distillate having an odour of pyridine was obtained; at the end of the operation, a few drops of unchanged sparteïne distilled. The aqueous solution thus obtained was neutralised with sulphuric acid and distilled twice, the second time with the addition of hydrochloric acid. The residues in each case were converted into platinochlorides; on concentrating the aqueous solution, sparteïne platinochloride separated. The mother liquors, after concentration and addition of alcohol, yielded two platinochlorides, the more soluble one melting at 238—240°, and the other at 178°. The first consisted of pyridine platinochloride, whilst the second, of which only a very small quantity was obtained, was possibly α-picoline platinochloride. W. J. P.

Quinine Methiodides. By E. Grimaux (*Compt. rend.*, **115**, 117—120).—When quinine dimethiodide is allowed to remain in contact with dilute aqueous potash in the cold for about 24 hours, the principal product is resinous and easily soluble in alcohol, from which it will not crystallise, but there is also formed about 12 per cent. of a yellow, crystalline powder, almost insoluble in neutral solvents. The crystals are slender needles which melt with decomposition at about 280°; they dissolve easily in acids, forming brownish-yellow, gelatinous salts, and the compound is reprecipitated by alkalis. Dilute solutions in alcohol, acetic acid, &c., have an intense, brilliant fluorescence. This compound has, in all probability, a high molecular weight, and is not formed by simple removal of hydriodic acid from the quinine dimethiodide; the proportion of iodine in the compound is lower than that required by the formula $C_{20}H_{24}N_2O_2\cdot OH,MeI$.

Methoxyquinoline methiodide, when treated with dilute aqueous potash, yields a crystalline, orange-yellow powder, in all respects similar to that obtained under similar conditions from quinine dimethiodide. It follows that the methyl iodide removable by potash from the quinine derivative is united with the methoxyquinoline group in the quinine molecule, and, since in quinine monomethiodide the methyl iodide is not removable by potash, it follows that the constitution of the monomethiodide is $C_{10}H_7(OMe)NO\cdot C_9H_{14}ONMeI$. The nitrogen not belonging to the quinoline nucleus is the more strongly basic, and it would seem that the most probable constitution of the basic salts of quinine is $C_{10}H_7(OMe)NO\cdot C_9H_{14}ON,HCl$ and $[C_{10}H_7(OMe)NO\cdot C_9H_{14}ON]_2,SO_4H_2$.

When basic quinine sulphate is boiled with excess of methyl iodide in presence of methyl alcohol, it yields quinine dimethiodide, and sulphuric acid is liberated. It would seem that the quinine salt partially dissociates in the boiling methyl alcohol, and the dissociation continues in consequence of the union of the liberated quinine with the methyl iodide. C. H. B.

The Hydriodo-compounds of the Cinchona Alkaloïds. By E. Lippmann and F. Fleissner (*Monatsh.*, **13**, 429—439; compare Abstr., 1891, 1517; this vol., p. 81; Skraup, this vol., pp. 83, 640).—Skraup and his co-workers have recently described a series of dihydriodides of certain cinchona alkaloïds, in which they regard both iodine atoms as combined with carbon atoms; the authors' investigations had led them to believe that the second molecule of hydrogen iodide was combined with the nitrogen atom, and they have therefore repeated Skraup's work, obtaining results which support their former conclusion. The monhydriodides containing the iodine in combination with the carbon behave as bases, the dihydriodides as normal salts, and the trihydriodides as acid salts.

Hydriodocinchonine hydriodide, $C_{19}H_{23}N_2OI,HI$, is formed by making a cinchonine solution neutral or slightly acid with hydriodic acid, and, after crystallisation from water and alcohol, melts at 187—190°; an excess of acid converts it into the trihydriodide already described. The *hydrochloride* and *nitrate* of hydriodocinchonine have also been prepared, and crystallise well.

When quinidine is treated with an excess of hydriodic acid, it is converted into the trihydriodide described by Skraup; this is converted, by the continued action of dilute ammonia, into *hydriodoquinidine*, the reaction not stopping with the formation of the dihydriodo-derivative, as supposed by Skraup; there is, therefore, no reason to suppose that in this compound the second iodine atom is also combined with the carbon. The following salts of hydriodocinchonine have also been prepared: the *platinochloride*, $C_{20}H_{25}N_2O_2I,H_2PtCl_6$, crystallising in orange-yellow plates; the *acid sulphate*,

$$C_{20}H_{25}N_2O_2I,H_2SO_4,3H_2O,$$

in silky needles; the *normal nitrate*, $C_{20}H_{25}N_2O_2I,HNO_3$, in feathery needles; the *acid nitrate*, $C_{20}H_{25}N_2O_2I,2HNO_3$, in strongly-refractive prisms; and the *acid hydrochloride*, $C_{20}H_{25}N_2O_2I,2HCl$, in feathery groups of silky needles. The *hydriodide*, $C_{20}H_{25}N_2O_2I,HI$, is obtained by the action of the theoretical quantity of ammonia on the trihydriodide, and has the physical properties ascribed to it by Skraup.

Skraup and Schubert, in their investigation of the action of ammonia on quinine trihydriodide, came to the conclusion that the product was a mixture of two distinct bases, of the composition $C_{20}H_{25}N_2O_2I$ and $C_{20}H_{26}N_2O_2I_2$, respectively, and that the original product was a mixture of two isomeric salts, $C_{20}H_{25}N_2O_2I,HI$ and $C_{20}H_{26}N_2O_2I_2,2HI$. The latter conclusion the authors find to be incorrect, the substance examined being, in reality, incompletely decomposed. If the mixture of the trihydriodide and aqueous ammonia is shaken with ether and allowed to remain, asymmetric crystals separate, containing ether of crystallisation and having the composition $C_{20}H_{25}N_2O_2I + Et_2O$; if kept over sulphuric acid in a vacuum, they lose $\frac{1}{2}$ mol. ether, the latter being completely removed in a current of hydrogen at 60°. Hydriodoquinine is thus obtained as a voluminous, dull, white powder, which melts at 150—155°, but commences to decompose at a much lower temperature.

H. G. C.

Condensation of Aldehydes with Benzoylpiperidine. By L. Rügheimer (*Ber.*, **25**, 2421—2429; see also Abstr., 1891, 1246).—The author finds that the compound obtained by treating benzoylpiperidine with benzaldehyde has the composition $C_{19}H_{17}N$, and not $C_{19}H_{19}N$, and is dibenzylpyridine.

Dibenzylpyridine, $C_5NH_3(CH_2Ph)_2$, is obtained by heating benzaldehyde (6 parts) with benzoylpiperidine (5 parts) in a sealed tube at 240—250° for six hours. The product is dissolved in ether, the ethereal solution shaken with sodium hydroxide and then with dilute hydrochloric acid. The base is obtained in the aqueous layer as hydrochloride, which sinks as a heavy oil crystallising after a time, and is purified by boiling it with a small quantity of benzene and allowing it to crystallise. The *free base* is obtained by dissolving the hydrochloride in chloroform and shaking the solution with sodium hydroxide; it crystallises from alcohol in thin tablets and scales, melts at 89°, and is easily soluble in alcohol, ether, and chloroform. It is a feeble base, and the salts are decomposed by water. The *hydrochloride* crystallises from benzene in large plates and scales, falls

to a powder on exposure to air, melts under boiling benzene, and, when dry, melts at 164·5—166°. The *hydrobromide* crystallises from benzene in thin plates, melts at 148·5° (uncorr.), and falls to powder on exposure to air. The *methiodide* is an oil which will not crystallise, and when its solution in chloroform is evaporated, yields leaflets which contain chloroform, and become oily on exposure to air. The *ethiodide* crystallises from alcohol in small needles, melts at 137°, is sparingly soluble in water, very sparingly so in benzene, but easily in chloroform.

Dibenzoylpyridine, $C_5NH_3Bz_2$, is obtained by heating the above base (1 part) with potassium dichromate (4·5 parts) and sulphuric acid (7 parts) in a reflux apparatus for 6—8 hours. The product is dissolved in acetic acid, the filtered solution diluted, treated with excess of sodium hydroxide, and the precipitate thus formed is dried at the ordinary temperature and extracted with boiling ether. It crystallises from alcohol in long needles, melts at 123°, is somewhat soluble in hot water, and is a feeble base. The *platinochloride* is obtained in long, bright, reddish-yellow needles, and cannot be recrystallised without decomposition.

When dibenzylpyridine (8 grams) is treated with chromic anhydride (75 grams) and sulphuric acid (260 grams diluted with twice its volume of water), it yields benzoic acid, benzoylpyridinecarboxylic acid, and pyridinedicarboxylic acid. The dicarboxylic acid does not melt at 290°, and the author believes it to be the 3.5-acid.

Tribenzylpyridine, $C_5NH_2(C_7H_7)_3$, is obtained in a similar way to the dibenzyl compound, by employing a larger proportion of benzaldehyde. It is insoluble in ether, crystallises from amyl alcohol, in which it is sparingly soluble, in small leaflets and plates, melts at 278—280°, and is very sparingly soluble in alcohol, easily so in acetic acid. E. C. R.

2 : 3-Dipiperidyl. By F. Blau (*Monatsh.*, **13**, 330—343).—The author has corrected and extended his previously published work on this compound (compare Abstr., 1891, 583). The base, when purified by distillation with steam, is a powerful alkali, boils at 267—268°, and melts at 68—69°. The true melting point is, in all probability, somewhat higher than this, for the compound rapidly absorbs water and carbonic anhydride from the air, and the temperature of fusion is thereby lowered. The *platinochloride*, $C_{10}H_{20}N_2,H_2PtCl_6 + 2H_2O$, is readily soluble in water, melts at 237—238° and loses its water of crystallisation at 100° ; the *aurochloride*, $C_{10}H_{20}N_2,2HAuCl_4$, melts at 211—212°, and the *picrate* at 215°. *Nitrosodipiperidyl*, $C_{10}H_{19}N_2(NO)_2$, has the characteristic odour of the nitrosamines, is not readily soluble in water unless a free acid is present, melts at 87·5—88·5°, and on long-continued warming with concentrated hydrochloric acid is partly reconverted into the original base. The compound of 2 : 3-dipiperidyl with carbon bisulphide crystallises well, and melts at 205° with decomposition.

The author has also carried out the reduction of nicotine according to Liebrecht's method (Abstr., 1886, 161), but has obtained a mixed product in lieu of that investigator's so-called dipiperidyl (hexahydro-

nicotine), which boils at 250—252°. It boils at 235—265°, and has not yet been completely investigated. G. T. M.

Hyoscine. By A. Ladenburg (*Ber.*, **25**, 2388—2394).—An answer to a paper by Schmidt (this vol., p. 1255). Schmidt has stated his belief that hyoscine, $C_{17}H_{23}NO_3$, does not exist, but is identical with scopolamine, $C_{17}H_{21}NO_4$, and says that the author's analyses agree better with the latter than with the former formula. The author quotes analyses which show that this is not the case. The basic decomposition product of hyoscine, that is, pseudotropine, also gave on analysis of its salts numbers agreeing with the author's formula.

The author has again analysed hyoscine aurochloride,

$$C_{17}H_{23}NO_3,HAuCl_4,$$

and pseudotropine platinochloride $(C_8H_{15}NO)_2,H_2PtCl_6$, and confirms his former results.

Pseudotropine platinochloride crystallises in the rhombic system; $a : b : c = 0{\cdot}70586 : 1 : 1{\cdot}39935$. These crystals are crystallographically distinct from those of scopoline platinochloride.

The author has examined a commercial sample of hyoscine, and finds that it contains scopolamine. This is, however, of no consequence commercially, as the two compounds have the same therapeutic action.

The author suggests the name *isidiom* for compounds which have different compositions but are very similar in chemical behaviour: such compounds are hyoscine and scopolamine, pseudotropine and scopoline, cobalt and nickel, niobium and tantalum pentachlorides, benzene and thiophen, &c. E. C. R.

Alkaloïds of the Root of Corydalis cava. By M. Freund and W. Josephy (*Ber.*, **25**, 2411—2415).—The product which the authors employed was obtained from Trommsdorff's manufactory, in Erfurt, and is prepared as follows:—The finely-cut roots are extracted with alcohol, the alcohol distilled off, and the aqueous solution which remains filtered from resin; ammonia is then added to the filtrate, and the precipitated base extracted with ether. On concentrating the ethereal solution, a product is first obtained which melts about 160°, but the mother liquors, if further concentrated and mixed with alcohol, yield a crystalline precipitate, which is purified by recrystallisation from alcohol. The product thus obtained melts at 126—130°, and is known as "corydaline"; the authors have examined it, however, and find that it consists of at least three alkaloids.

Corydaline, $C_{22}H_{27}NO_4$, melts at 134·5°. The authors confirm the results of Dobbie and Lauder (Trans., 1892, **61**, 244, 605).

Bulbocapnine, $C_{34}H_{36}N_2O_7$, is separated from corydaline by using excess of alkali, in which it is soluble, whereas corydaline is not. It melts at 198—199°, does not lose water when heated at 120°, and is bibasic.

Corycavine, $C_{23}H_{23}NO_5$, is contained in small quantity in the crude product melting at 126—130°, and in somewhat larger quantity in the product melting at 160°. It melts at 214—215°, crystallises in beautiful, rhombic tablets, is insoluble in alkali and less soluble in absolute alcohol than corydaline. The *hydrochloride*,

$$C_{23}H_{23}NO_5,HCl,H_2O,$$

the *hydriodide*, $C_{23}H_{23}NO_5,HI,H_2O$, and the *platinochloride*,

$$(C_{23}H_{23}NO_5)_2H_2PtCl_6,2H_2O,$$

do not lose their water of crystallisation when heated at 120—130°. The *methiodide* melts at 218°.

The authors have also examined preparations of corydaline obtained from E. Merck, of Darmstadt, and from T. Schuchardt, of Görlitz. The former contained corydaline and bulbocapnine. The latter contained corydaline and a small quantity of a base which is soluble in alkali, and melts at 205—207°.

The authors are engaged in the further study of bulbocapnine and corycavine. E. C. R.

A New Leucomaïne. By A. B. Griffiths (*Compt. rend.*, **115**, 185—186).—A considerable quantity of the urine of an epileptic was made alkaline with sodium carbonate, shaken with half its volume of ether, the filtered ethereal extract agitated with aqueous tartaric acid, and the alkaloïd precipitated from the acid solution by excess of sodium carbonate. It was then taken up with a fresh quantity of ether, and on evaporating the latter, was left as white, oblique prisms. The *leucomaïne*, $C_{12}H_{16}N_3O_7$, thus obtained, is soluble in water, is feebly alkaline in reaction, and forms a crystalline *hydrochloride* and *aurochloride*. It gives a greenish-white precipitate with mercuric chloride, a yellowish precipitate with silver nitrate, a white precipitate with phosphotungstic acid, a brownish-white precipitate with phosphomolybdic acid, and a yellow precipitate with tannin. It is poisonous, producing trembling, intestinal and urinary evacuations, dilatation of the pupils, convulsions, and death. Jn. W.

Physiological Chemistry.

Digestibility of Raw and Boiled Meat. By A. Stutzer (*Landw. Versuchs-Stat.*, **40**, 321—322).—Nearly all the results of experiments on the digestibility of meat show that it is made less digestible by being cooked. The author has investigated the matter, using his own method of fractional digestion. A large piece of beef was cut in half, the one half cut up, dried at 40°, and finely powdered. The other half was boiled in the usual manner, but without salt, cut up, dried at 40°, and powdered. The following analytical results were obtained:—

	Nitrogen per cent.			Moisture per cent.
	Non-proteïd.	Soluble in pepsin.	Insoluble in gastric juice.	
Raw meat.....	1·33	12·73	0·35	5·25
Boiled meat	0·49	13·07	0·43	6·92

The meat (about 4 grams) was then treated with dilute hydrochloric acid (0·05 and 0·2 per cent.) and with gastric juice containing 0·05 and 0·20 per cent. of hydrochloric acid; the percentage amounts of nitrogen digested were as follows:—

	Nitrogen dissolved.	
	Raw meat.	Boiled meat.
Gastric juice (0·05 per cent. HCl)....	89·2	38·7
,, ,, (0·20 ,, ,,)....	96·9	79·3
Hydrochloric acid (0·05 per cent.)....	29·0	9·6
,, ,, (0·20 ,,)....	52·2	13·2

Boiling thus diminishes the digestibility of meat, the difference being most considerable when a small amount of hydrochloric acid is used. N. H. M.

Presence of Pentamethylenediamine in Pancreas Extracts. By B. Werigo (*Chem. Centr.*, 1892, i, 487—488; from *Pfluger's Arch.*, **51**, 362—366).—The finely-divided pancreas is digested for 24 hours with five times its weight of water, together with a little chloroform, heated to boiling, and filtered. On adding picric acid to the filtrate, a precipitate is formed, which is principally amorphous, but also includes some crystalline substance. As obtained by the author, this substance appeared to be isomeric with Brieger's cadaverine. Whether it is formed by fermentation or not is doubtful.

In one specimen which had been prepared six months previously and was still sterile, a little of this substance could be detected; the author thinks it probable that it is formed by the action of an enzyme. J. W. L.

Human Succus Entericus. By A. H. Tubby and T. D. Manning (*Guy's Hosp. Rep.*, **48**, 271—298).—A case is recorded in which by surgical interference a Vella's fistula was made. The pure intestinal juice was collected by means of a sponge, or an appropriate bottle strapped to the patient's side. The daily average quantity was about 25 c.c. Its reaction was alkaline; its average sp. gr. 1·0069. By artificial digestion experiments, it was found to cause a flocculent precipitate (caseïnogen?) in milk, the milk turning acid; it also prevented the gelatinisation of gelatin. It had no proteolytic action on proteïds. It emulsified and saponified fats. But the most important property of the juice appeared to be its action on carbohydrates. This is in accordance with the most trustworthy previous work on

the subject. Cellulose was unaltered; starch was in 56·5 per cent. of the experiments converted into dextrose; and in 60 per cent. of the experiment, sucroses (cane sugar and maltose) were converted into glucose. Succus entericus thus continues the action of the salivary and pancreatic ferments. A glycerine extract of the mucous membrane was made which acted in the same way. W. D. H.

Influence of Oxygen on the Separation of Carbonic Anhydride in the Lungs. By B. Werigo (*Chem. Centr.*, 1892, i, 488; from *Pfluger's Arch.*, **51**, 321—361).—In order to determine whether or not oxygen displaces carbonic anhydride from the blood in the lungs merely by the laws of gaseous diffusion, the author caused each lung of the same animal to work independently of the other. To the one lung, a gaseous mixture rich in oxygen; to the other, an inert gas (hydrogen) was supplied. The results corroborate those obtained by Pflüger, and afford further evidence that the carbonic anhydride is displaced by oxygen in accordance with the ordinary laws of gaseous diffusion. J. W. L.

Combination of Hæmoglobin with Oxygen. By C. Bohr (*Chem. Centr.*, 1892, i, 486—487; from *Skand. Arch. Physiol.*, 1891, iii, 76).—The author distinguishes between different oxyhæmoglobins (Abstr., 1890, 1450) which absorb different quantities of oxygen.

The α-modification may be obtained in solution if the solution of the β-modification is placed in a vacuum, and then shaken with air. From the usual crystalline γ-modification the β-modification may be obtained by repeatedly drying and redissolving the crystals. The γ-modification may be obtained directly from blood by separating the blood corpuscles by means of a centrifugal machine, and then washing with sodium chloride solution to which a little ether has been added. The δ-modification was frequently formed in some specimens of the γ-modification which had been preserved in solution in sealed tubes.

There appears to be no uniform relation between the quantities of absorbed oxygen, the dry substance, the proportion of iron, and the absorption of light of the several modifications. The proportion of iron varied from 0·32 to 0·47 per cent., and the relative molecular weight varied very greatly. J. W. L.

Sensitiveness of the Hæmatin Spectrum and the Formation of Hæmin Crystals as Proof of the Presence of Blood. By G. Janeček (*Chem. Centr.*, 1892, i, 507—508).—Of the three methods which are generally employed for the detection of blood, the microscopical examination of the corpuscles, the examination of the hæmatin spectrum, and the preparation of hæmin crystals, the former is undoubtedly the best, provided that the material at command will admit of such an examination. The author has, however, made some very interesting observations regarding the blood and excrement of insects, such as fleas and bugs, which live on higher animals. He finds that not only the blood, but also the excrement contains the perfect blood corpuscles of the higher animals from which it was originally obtained. Consequently the

spectrum of these materials was very similar to that of the blood of the higher animal, and the hæmin crystals could be obtained in quantity. J. W. L.

Hæmocyanin. By L. Fredericq (*Compt. rend.*, **115**, 61).—The author confirms the statements of Krukenberg, Halliburton, Griffiths, and others. He considers that the negative results obtained by Heim (this vol., p. 898) are due to the fact that Heim made his experiments with the cray fish, lobster, crab, &c., in which the quantity of hæmocyanin is very small. C. H. B.

Respiratory Value of Hæmocyanin. By L. Cuénot (*Compt. rend.*, **115**, 127—129).—The author has compared the quantity of oxygen present in the blood of *Helix pomata* with the quantity dissolved in the distilled water of the laboratory. The results show that the blood contained from 11 to 12 c.c. of oxygen per litre, a quantity considerably greater than is dissolved by water in contact with air.

It follows that hæmocyanin has a distinct power of absorbing oxygen, although in this respect it is much inferior to hæmoglobin. It would seem, therefore, to have a true respiratory function, but this is so feeble that the replacement of the hæmocyanin by a colourless proteïd which has no chemical attraction for oxygen does not materially affect the vital processes of the organism. As a matter of fact, under similar conditions, allied species occur, some with and some without hæmocyanin. The presence of hæmoglobin in invertebrata, on the other hand, is generally observed where the conditions of life are difficult, especially as regards the supply of oxygen required for respiration (compare this vol., p. 898 and preceding abstract). C. H. B.

Cause of the Rapid Curdling of Milk during Thunder Storms. By Liebig (*Chem. Centr.*, 1892, i, 490—491; from *Milch. Zeit.*, 1891, No. 27).—Experiments made with a view of demonstrating whether the increased proportion of ozone present in the atmosphere at the time of thunder storms is the cause of the rapid curdling of milk gave negative results; and the author considers that it is the high temperature which usually accompanies such atmospheric conditions which indirectly causes the souring; such temperatures being favourable to rapid fermentation. J. W. L.

Chemistry of Vegetable Physiology and Agriculture.

Calcium Oxalate in the Bark of Trees. By G. Kraus (*Ann. Agron.*, **18**, 271—272).—As the result of his experiments on the barks of various trees which contain calcium oxalate in quantity, the author concludes that this is a reserve deposit and not an excretion, and that it is redissolved in spring and summer according to the

needs of the plant. Branches of *Ribes sanguineum* lost, from December 16th to April 27th, 16·62 per cent. of their oxalate; from March 13th to April 3rd, 13·17 per cent.; and to April 16th, 38·07 per cent. Similar results were obtained with other trees. The author remarks that calcium oxalate is certainly liable to solution by long-continued action of an acid circulating liquid like cell-sap.

J. M. H. M.

Occurrence in Plants of a Gum giving rise to Xylose by Saccharification. By A. Hébert (*Ann. Agron.*, **18**, 261—267).—The author points out that the probability of the formation of carbohydrates in plants by the polymerisation of formaldehyde is strengthened by the recent discoveries of carbohydrates having other than 6 atoms of carbon: the pentaglucoses, such as arabinose and the xylose of Wheeler and Tollens; and the heptaglucose formed by Muntz and Marcano by hydrolysis of the perseïtol ($C_7H_{16}O_7$) extracted from *Laurus persea*.

The wood-gum yielding xylose by saccharification, originally found in several species of wood by Wheeler and Tollens, has since been found in large quantity by the author in oat straw and wheat straw; he now shows that the hay of grasses contains it in quantity, and that lucerne contains little or no starch, but is rich in the same straw- or wood-gum. Flax straw also contains much of it.

The melting point and rotatory power of the sugar produced by hydrolysis of the gum extracted from these products agree with those of xylose, as do the melting point and character of the crystalline osazone which it yields by treatment with phenylhydrazine. By a less direct test (namely, the production of furfuraldehyde, a characteristic product of the pentaglucoses when acted on by boiling mineral acids) the author infers the presence of the same gum in many other vegetable products, including beet and potato pulp residues and the leaf mould of gardeners.

J. M. H. M.

Preparation of Teas. By Y. Kozai (*Bied. Centr.*, 1892, 488—489).—Young leaves gathered from tea shrubs of different ages, but growing on the same plot of ground, show no definite variation in their composition which can be attributed to the age of the plant. If the shrub, for three weeks before picking, be encased so as to exclude the light, the leaves are etiolated, and vary in composition from those grown in full light.

	Grown in the dark.	Grown in the light.
Theïne	4·532 p. c.	3·784 p. c.
Total nitrogen	7·835 „	6·945 „
Nitrogen in theïne	1·311 „	1·094 „
Percentage of theïne nitrogen on total nitrogen...	16·72 „	15·75 „

The percentage of tannin is not affected by excluding the light. In Japan, the finest tea, after powdering, is consumed with the liquor: by another method the leaves are steeped for two minutes in water at 50—60°; a poorer quality is obtained by treatment for one minute

in boiling water: by the use of water at 50° three extractions may be made, each differing very slightly from one another in composition; whilst if the water is at 100°, then nearly all the soluble matter is removed by the first steeping. E. W. P.

Influence of Phosphoric Acid on the Formation of Chlorophyll. By O. Loew (*Ann. Agron.*, **18**, 270—271).—Hoppe-Seyler, in 1879, found that "crystallised chlorophyll" contained 1·38 per cent. of P_2O_5; and later, that chlorophyll, when treated with boiling alcoholic potash is resolved into choline, glycerophosphoric acid, and the acid of chlorophyllane, and suggested that chlorophyll is probably a kind of lecithin in which the acid of chlorophyllane plays the part of a fatty acid. Struck with this view, and following up an observation of his own, the author cultivated *Spirogyra majuscula* in a nutrient solution containing, per thousand, 0·2 of calcium nitrate and 0·02 of ammonium sulphate. The cultures were made in stoppered flasks, into which a little carbonic anhydride was introduced from time to time. Elongation of the cells took place, but the increase in mass was insignificant, cell division not being noticed. Many cells had become swollen, and had given out lateral tubes, as if in preparation for conjugation. The chlorophyll layer was pale and yellowish, but continued its movements, although sluggishly. On adding 0·02 per 1000 of ferrous sulphate and dividing the cultures into two lots, to one of which was added 0·08 per 1000 of disodium phosphate, a great difference was observed. After five days, those cultures which received phosphoric acid became dark green, cell division took place, and the chlorophyll movement became lively. The cultures receiving iron alone did not show this recovery. J. M. H. M.

Analyses of Apple Tree Leaves. By F. T. Schutt (*Bied. Centr.*, 1892, 493—494).—The following is the average composition of leaves from five varieties of apple trees, collected on May 25th and September 20th:—

	May 25th.	Sept. 20th.
Water	73·36 per cent.	60·71 per cent.
Ash	2·33 ,,	3·46 ,,
Nitrogen	2·94 ,,	2·48 ,,
	In Ash.	
P_2O_5	10·47 ,,	5·82 ,,
K_2O	10·82 ,,	11·63 ,,
CaO	17·40 ,,	27·91 ,,
MgO	9·77 ,,	4·81 ,,
Fe_2O_3	3·49 ,,	1·41 ,,
SiO_2	1·07 ,,	1·14 ,,

E. W. P.

Analyses of Healthy and Diseased Sugar Cane. By A. Stutzer (*Landw. Versuchs-Stat.*, **40**, 325—327).—The sugar canes were sent from Cheribon, in Java, in 1884, when there was much disease. The healthy plant was 2—2·5 m. high, and the average

circumference of the stalk 9—11·5 cm.; the pith was white. The diseased cane (of the same age as the other) had stalks 50—60 cm. high, and many less. Many plants had no stalks, the leaves growing from the root stem; the leaves were smaller than those of the healthy plant, and the pith was more or less brown, and was frequently wanting altogether. The following table shows the percentage of ash constituents in the dry substance of (I) healthy leaves, (II) diseased leaves, (III) healthy canes, (IV) diseased canes:—

	SiO_2.	SO_3.	P_2O_5.	Fe_2O_3.	CaO.	MgO.	K_2O.	Na_2O.	Cl.
I...	3·032	0·466	0·307	0·053	0·080	0·310	2·022	1·504	0·552
II...	9·348	0·384	0·467	0·509	0·310	0·360	1·213	1·945	0·694
III...	0·950	0·154	0·269	0·067	0·040	0·063	0·990	0·690	0·150
IV...	1·504	0·305	0·410	0·048	0·035	0·056	1·640	0·516	0·309

The percentages of nitrogen were—(I) 0·65, (II) 0·76, (III) 0·35, (IV) 0·64.

The differences in the ash constituents are considerable, especially in the case of potash and silica, and when the analyses of the healthy cane are compared with earlier analyses (Knop, Abstr., 1883, 110; 1884, 1212), it is seen that the amounts of lime and magnesia are low, whilst that of soda is very high. The results with the analyses of the soil in which the plants were grown indicate that a manuring with potash and lime is most necessary, especially as sugar cane is known to thrive well in a calcareous soil. Almost the only manure employed is "böngkil," consisting of earth-nut cake containing a good deal of oil, about 5 per cent. of nitrogen, and scarcely 1 per cent. of phosphoric acid and potash respectively. N. H. M.

Some Properties of Humin and Humic Acid. By Miss A. Rodzyanko (*J. Russ. Chem. Soc.*, **22**, 208—229).—Experiments of the authoress on earth obtained from the Government of Poltawa have shown that, when minerals are acted on by humic acid, acid salts are formed, and also other compounds, containing the elements of the minerals united with the radicle of this acid. Humin absorbs various inorganic substances from aqueous solution, such as the salts of sulphuric, hydrochloric, phosphoric, and carbonic acids, solutions of aluminium chloride and of alkaline silicates. Humic acid dissolves and decomposes several otherwise insoluble inorganic compounds; it decomposes the silicates. Compounds which belong to the class of alcoholic derivatives are formed.

Humin compounds already containing a given element absorb substances containing this element more readily than other substances; it seems that metallic derivatives of humic acid are stronger acids than the original acid, and the constitution of the metallic derivatives of organic compounds present in a given sample of earth naturally depends on its original composition. M. F.

Analytical Chemistry.

Improved Gas Pipette. By A. H. Gill (*Zeit. anal. Chem.*, **31**, 292—293).—In place of the four-bulb Hempel pipette, the author uses that with two bulbs only, but attaches an india-rubber ball to the wider tube. This protects the reagents as effectually as the water lute, and is more convenient in use. M. J. S.

Errors arising in Chemical Operations owing to the Employment of Gas Flames. By A. Lieben (*Monatsh.*, **13**, 286—298).—Coal-gas contains an appreciable amount of combined sulphur; and, when its flame is directly employed in the evaporation of solutions contained in open dishes, sulphur, in the form of sulphuric acid, can be usually recognised in the solutions. The quantity of sulphur absorbed as sulphuric acid by any particular liquid, during evaporation, depends not only on the size of the flame and on the duration of the process, but also on the chemical properties of the liquid in question. The largest quantity of acid is absorbed by solutions of substances having a basic nature, and by those containing the salts of volatile organic acids. Much less sulphur is absorbed during the evaporation of distilled water, and very little indeed by a solution of barium chloride acidified with hydrochloric acid. Pure hydrochloric acid does not take up even a trace of sulphuric acid.

Under some conditions, sulphurous anhydride can be recognised amongst the products of combustion of coal gas; but even then it is produced only in very small quantities. The formation of sulphuric acid must not therefore be regarded as due to the oxidation of the lower oxide. This view is confirmed by the fact that when a platinum dish filled with water is placed over a Bunsen flame, the dewy deposit, which immediately forms on the outside, contains a considerable quantity of sulphuric acid. On further heating, this water volatilises; but the sulphuric acid, owing to its high boiling point, remains on the platinum. G. T. M.

Extended Employment of Arsenious Acid in Volumetric Analysis. By R. Namias (*Gazzetta*, **22**, 508—513).—The author dissolves arsenious oxide (8 grams) in a concentrated aqueous solution (300—400 c.c.) of ammonium acetate (80 grams) by the aid of heat, and then dilutes to a known volume (1 litre). This solution is standardised against iodine solution of known strength (10 grams of iodine per litre) and need not be titrated in presence of sodium hydrogen carbonate, as equally accurate results are obtained when the solution contains free acetic acid. The titration with the acid solution is less rapid than with the ordinary alkaline solution, but can be performed more quickly at 60—70° with no diminution in accuracy.

The estimation of the active chlorine in bleaching powder may be conducted as follows:—The bleaching powder (10 grams) is triturated in a mortar with water and the liquid made up to a litre. 15 c.c. of the

standard arsenious oxide solution is added to 10 c.c. of the clear bleaching powder solution, heated to 60°, acidified with acetic acid, and the excess of arsenious solution titrated with iodine solution in presence of starch. Chloric acid may be estimated by adding the chlorate (0·5 gram) to the arsenious solution (20 c.c.), diluting to 50 c.c., adding excess of hydrochloric acid, heating at 100° for some time, and titrating with iodine. The determination of the active oxygen in manganese dioxide may be made in a similar manner.

Chromates and dichromates may be estimated in the same manner as manganese dioxide or in a solution acidified with acetic acid only; in this case the liquid must be boiled for at least 15 minutes before the titration is performed.

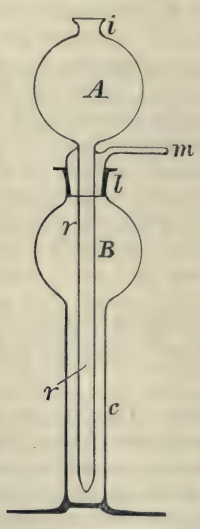
The volumetric estimation of lead may be carried out as follows:—An excess of potassium dichromate solution of known strength is added to the solution of the lead salt acidified with acetic acid. The liquid is now made up to a known bulk, and after complete subsidence of the precipitate an aliquot part of the solution is withdrawn and the excess of dichromate found by means of the arsenious solution. The results are accurate, but if the titration is performed in presence of the precipitate the results are somewhat less trustworthy.

W. J. P.

Presence of Lead in Glass Wool. By L. Blum (*Zeit. anal. Chem.*, **31**, 292).—A specimen of commercial glass wool was found to blacken when exposed to hydrogen sulphide, the blackening being due to the presence of lead. For the filtration of acids, or any operation in which the presence of lead would be objectionable, such wool must be avoided. M. J. S.

Gasometric Estimation of Nitric Acid. By Glaser (*Zeit. anal. Chem.*, **31**, 285—288).—In those methods which depend on the reduction of the nitric acid by hydrochloric acid and ferrous chloride, and measurement of the nitric oxide, there is always a liability to error from the presence of dissolved oxygen in the liquid over which the gas is collected, whereby part of the nitric oxide is converted into nitrous acid. This oxidation can be prevented by collecting the gas over a 1 per cent. solution of potassium iodide, when the well-known reaction between nitrous and hydriodic acids, resulting in the liberation of iodine and nitric oxide, occurs. In cases where carbonates are present the gas must be treated with soda, but in their absence this is unnecessary. The few test analyses communicated are perfectly satisfactory. M. J. S.

Estimation of Sulphur.—II. By F. P. Treadwell (*Ber.*, **25**, 2377—2382).—In a former paper (Abstr., 1891, 1137), the author has shown that sulphur can be determined in insoluble sulphides by heating them with iron in an atmosphere of carbonic anhydride, decomposing the sulphide of iron with hydrochloric acid, and absorbing the hydrogen sulphide in an ammoniacal solution of hydrogen peroxide. This method is applicable to the estimation of pyrites in slate if the compound contains no calcium sulphate. If sulphates are present they are reduced to sulphides.



The author finds that the sulphur of pyrites and of other insoluble

sulphides is quantitatively converted into hydrogen sulphide by treatment with tin and concentrated hydrochloric acid.

The analysis is carried out as follows:—The flask in which the decomposition takes place is covered on the bottom with a layer of tin powder 5 mm. thick, and the substance to be analysed, wrapped in tinfoil, is introduced and covered with 60 mm. of granulated tin. The air in the apparatus is then replaced by hydrogen, concentrated hydrochloric acid added, and the mixture heated for about 50 minutes; the hydrogen sulphide which is evolved being collected in hydrogen peroxide solution as previously described. The results obtained are good. The method is applicable to the estimation of pyrites in slate, but slightly high results are obtained.

With substances containing arsenic and antimony, large quantities of arseniuretted and antimoniuretted hydrogen are evolved. The author is engaged on experiments to determine if the reaction is quantitative. E. C. R.

Absorption Apparatus for Use in the Estimation of Sulphur in Iron. By L. Blum (*Zeit. anal. Chem.*, **31**, 290—292).—This consists of two parts, B, a cylinder, the upper part of which is expanded into a bulb of 200 c.c.; A, a tube *r*, drawn out to a point below, and with a 200 c.c. bulb blown on its upper portion, and carrying below its bulb a hollow stopper ground into the neck *l* of the cylinder, and furnished with a side tube *m*, for the escape of unabsorbed

gases. The cylindrical part of B is 20 cm. high, and holds about 50 c.c. In the cylinder is placed either a solution of bromine in hydrochloric acid, or ammoniacal hydrogen peroxide, and the neck *i* of the bulbed tube A is connected by a tube to the flask in which the iron is being dissolved. The whole is stood in a beaker of cold water

while the absorption is taking place. The absorption of the hydrogen sulphide is always complete, and regurgitation of the liquid is impossible.

When brominated hydrochloric acid is used as the oxidising agent, the difficulty in the filtration caused by the presence of resinous brominated hydrocarbons (Abstr., 1890, 921) may be got rid of by adding to the liquid a fragment of ash-free filter-paper before precipitating with barium chloride. This, during the subsequent boiling, breaks up into fibres, which entangle the brominated compounds, promote rapid subsidence of the precipitate, and allow filtration to proceed unchecked. M. J. S.

Volumetric Estimation of Sulphuric Acid in Urine. By E. Freund (*Chem. Centr.*, 1892, i, 607; from *Wien. klin. Woch.*, **51**, 958).—To 50 c.c. of urine (which must not be too strongly coloured) is added 10 drops of a 1 per cent. solution of sodium alizarinsulphonate, and then a 5 per cent. solution of acetic acid is added drop by drop, until the solution becomes orange-coloured; 5 c.c. more of acetic acid are now added, the solution heated nearly to boiling, and titrated with barium acetate until the precipitated barium sulphate appears distinctly red. The barium acetate solution contains 11·22 grams per litre. The experimental error amounts to about 2·5 per cent.

Very concentrated urines are diluted before titration. Strongly coloured urines should be decolorised by the addition of zinc-dust, and the dissolved zinc precipitated by means of sodium hydroxide. J. W. L.

Volumetric Estimation of Sulphates. By A. Bouriez (*Chem. Centr.*, 1892, i, 570—571; from *Rev. internat. fals. aliment.*, **5**, 118—120).—A standard solution of barium hydrogen phosphate is prepared, and with a measured quantity of this the solution of the sulphate is boiled; the barium must be in excess. After filtering from the precipitated barium sulphate, an excess of sodium carbonate is added to the filtrate, which precipitates the excess of barium as tribarium phosphate. This precipitate is washed until the washings are neutral to phenolphthaleïn. The precipitate is transferred to a beaker, dissolved in dilute hydrochloric acid, an excess of sodium sulphate is added to precipitate the barium, and the phosphoric acid is determined in the filtrate volumetrically by Jolv's method, which depends on the fact that methyl-orange reacts with phosphoric acid as a monobasic, whilst phenolphthaleïn reacts with it as a bibasic acid. The solution (which need not be filtered) is therefore coloured with methyl-orange, and standard sodium hydroxide added until the colour becomes orange, inclining to yellow; phenolphthaleïn is then added, and the titration continued until the rose colour appears. From the amount of phosphoric acid found, the amount of sulphuric acid may be calculated. J. W. L.

Estimation of Calcium Salts in Syrup and Sugar Products. By J. Wolf (*Chem. Centr.*, 1892, i, 650; from *Österr.-ungar. Zeit. Zuck.-ind.*, **21**, 96—104).—For this purpose a soap solution is prepared as follows:—150 grams of pure olive oil is warmed on

the water-bath with 5 c.c. of water; 100 grams of finely powdered litharge and a solution of 5 grams of lead acetate in 40 c.c. of water are added, and the whole is stirred until homogeneous. This lead plaster is washed with water and rubbed down (150 grams) with potassium carbonate (40 grams) to a uniform paste, which is extracted with strong alcohol. The lead carbonate is filtered off and the filtrate distilled; 40 grams of the residual soap is then dissolved in 1000 c.c. of alcohol of 56 Tralles. To bring this solution to such a strength that 1 c.c. shall correspond to 0·0005 gram of CaO, 100 c.c. of a solution of calcium chloride (0·15 gram per litre) is introduced into an Erlenmeyer flask, and 25 c.c. of a pure sugar solution of 13° S. (?) added, together with a few drops of strong ammonia; it is then made up to 150 c.c. with water. To this mixture the soap solution is added until a final drop produces a lather about 1 cm. thick, and permanent for 10 minutes. The operation is repeated with the same quantity of the same sugar solution, omitting the calcium chloride solution. The difference between the number of c.c. used in each case is the quantity of soap solution equivalent to 100 c.c. of the calcium chloride solution.

The above solution will serve for titrating the calcium salts in sugar products, provided:—(1) That the liquid is neutral or slightly alkaline. (2) That a few drops of strong ammonia are present. (3) That the quantity of soap solution added does not exceed 20 c.c.; otherwise lime soap separating on the surface will render the end reaction indistinct. (4) When titrating second or third products, the syrups are dissolved in water at about 40°. (5) That the lather is about 1 cm. thick, is clear, vesicular, and permanent for 10 minutes; when the lather has disappeared, it should be easily reproduced by re-agitation.

A. G. B.

Separation and Estimation of Lead, Silver, and Zinc in Galena and Blende. By E. Aubin (*Bull. Soc. Chim.* [3], **7**. 134—135).—The author recommends the following rapid process for the commercial analysis of galenas and blendes. The powdered mineral (10 grams) is treated with fuming nitric acid (50 c.c.) in a conical flask (1 litre); the whole is then evaporated to dryness on the sand-bath, taken up by nitric acid (20 c.c. of sp. gr. 1·33), and the solution diluted to about 400 c.c. with water. The siliceous gangue and lead sulphate are now collected on a double tared filter, and after being washed, dried, and weighed, the lead sulphate is extracted from the weighed precipitate by trituration in a glass mortar with hot sodium tartrate solution (20 per cent.). The siliceous gangue remains unchanged, and is again collected on the tared filters and weighed; the weight of lead is thus determined. The liquid containing the silver and zinc is now made up to a standard volume (500 c.c.); in part of this (50 c.c.), after separating the iron and aluminium by ammonia, the zinc is precipitated with ammonium hydrosulphide, and the precipitate collected and dissolved in hydrochloric acid; the solution after being filtered is precipitated hot with sodium carbonate, and the zinc weighed as oxide. The remaining liquid (450 c.c.), containing the silver, is rapidly evaporated to 20—30 c.c. and cooled, the clear solution is decanted from the

crystalline deposit, and pure sodium chloride (1 gram) added to it to precipitate the silver as chloride; this is then collected, dried, and weighed on a double tared filter. W. J. P.

Essence of Sandal Wood. By E. Mesnard (*Compt. rend.*, **114**, 1546—1547).—Adulteration of essence of sandal wood with terebenthene, oil of cedar, oil of cubebs, copaiva, &c., is detected by mixing it with concentrated sulphuric acid. When the essence is pure, the mixture is at first viscous, then becomes pasty, and very rapidly changes to a pale bluish-grey or greyish, solid mass which adheres strongly to glass; when impure, the viscous mixture does not completely solidify, has a dark colour and a very distinct lustre. If 2 to 3 centigrams of the essence is mixed with a drop of strong sulphuric acid and poured on a ground glass plate, and the end of a small glass rod attached to the under side of a balance pan is inserted in the viscous mixture, the degree of adherence of the solidified mass can be measured, and the amount of adulteration roughly estimated. C. H. B.

Detection of Higher Alcohols in Spirits of Wine. By C. Bardy (*Compt. rend.*, **114**, 1201—1204).—A preliminary examination is made by agitating 10 c.c. of the alcohol with 100 c.c. of a saturated salt solution. If an oily upper layer does not separate, 100 c.c. of the alcohol is agitated with 450 c.c. of a saturated salt solution in a vessel provided with a stop-cock; sufficient water is added to redissolve the salt that is precipitated, and then 60 to 70 c.c. of carbon bisulphide, and the mixture is well agitated. After a short time, the bisulphide is transferred to a smaller similar vessel, and the extraction is repeated a second and third time with similar quantities of carbon bisulphide, the whole of the latter being transferred to the second vessel. In order to separate the alcohols from the bisulphide, the latter is mixed with sufficient concentrated sulphuric acid (about 2 c.c.) to form a heavier layer at the bottom of the vessel, and, after vigorous agitation, the acid is transferred to a smaller vessel. The extraction is repeated several times with 1 c.c. of acid each time, and the various quantities of acid are mixed, heated at 50—60°, and a current of air passed over the surface of the liquid until all the bisulphide is expelled. An equal volume of glacial acetic acid is then added, and the mixture heated on a water-bath at about 100° for a quarter of an hour, the flask being fitted with a reflux condenser. When the action is complete, the contents of the flask are poured into 100 c.c. of saturated salt solution. If higher alcohols were originally present, the corresponding acetates separate and form an upper layer, the volume of which can be measured by any of the usual methods, the liquid being previously cooled to 15°. The number of cubic centimetres of acetates multiplied by 0·8 gives the percentage of higher alcohols in the alcohol examined.

If in the preliminary test an oily upper layer separates, only 25 c.c. of the alcohol should be taken and mixed with 100 c.c. of saturated salt solution and 8 to 10 c.c. of water. The quantity of carbon bisulphide, however, ought not to be reduced, and all the other operations are conducted in the manner described.

The carbon bisulphide dissolves only butyl and amyl alcohols, and if propyl alcohol is sought for, the salt solution that has been extracted with bisulphide is filtered and distilled until an alcoholometer in the receiver marks 50°. The quantity of propyl alcohol in the distillate is estimated by titration with permanganate (Barbet) or by Gossart's method.

Alcohol in the distillery residues known as "essential oils" may be determined by a modification of this method. 500 c.c. is agitated with an equal volume of salt solution, and the latter is extracted with three successive quantities of carbon bisulphide and afterwards distilled. The alcoholic strength of the distillate, corrected, if necessary, for the presence of propyl alcohol and calculated to the original volume, gives the percentage of alcohol present.

This method will detect 0·5 per cent. of higher alcohols in spirits of wine. Greater sensitiveness can be obtained by working with a larger quantity of the alcohol, but in this case a correction must be made on account of the ethyl acetate formed from the alcohol dissolved by the carbon bisulphide. C. H. B.

Reactions of Amidobenzoic Acids. By O. de Coninck (*Compt. rend.*, **114**, 1275—1276).—Orthoamidobenzoic acid, when heated with a slight excess of pure potassium nitrite, yields a substance that forms a garnet-red solution in dilute alcohol. The para- and meta-acids form compounds which yield orange-red solutions.

When heated to fusion with a slight excess of ammonium nitrate, the acids form two layers, the lower pale red and the upper violet. With a smaller proportion of the salt, a deep coloration is formed, sometimes red, sometimes brown, and if the substance is cooled for a short time and mixed with a little water, a colourless solution is formed which regains the original colour on heating.

Uranium nitrate, on heating gently, yields a sublimate which is bright red with the ortho-derivative, and forms an amber-yellow alcoholic solution; brown with the meta-acid, and forms a red-brown alcoholic solution; orange with the para-acid, and forms a deep-yellow alcoholic solution.

Bleaching powder, when heated gently with the ortho-acid, yields a deep-violet magma, forming a red solution with concentrated alcohol, which after a time shows a violet fluorescence. The para- and meta-acids also yield red solutions under the same conditions, but they show no fluorescence.

Zinc chloride heated just to fusion gives an amber-coloured mass with the ortho-acid, deep violet with the meta- and para-acids.

Stannous chloride on heating gives yellow products with all three acids.

Stannic chloride acts energetically on the ortho-acid. The solution of the product in dilute alcohol is red. The meta- and para-acids give no reaction, except that sometimes the meta-acid yields a small quantity of violet sublimate. C. H. B.

General and Physical Chemistry.

Hasselberg's so-called Second or Compound Hydrogen Spectrum and the Structure of Hydrogen. By A. Grünwald (*Monatsh.*, **13**, 111—244).—Balmer showed that the wave-lengths of a portion of the rays in the line spectrum of hydrogen, emitted at high temperature, are in simple rhythmical relation one to another. At low pressures and temperatures, hydrogen emits not only the above rays, but a number of other relatively weaker ones, forming the so-called second or compound line spectrum, which has been specially described by Hasselberg. The lines in this second spectrum do not appear at first sight to bear any relations one to another, but the author, who has been engaged in a very complete and lengthy investigation of this point, finds that certain regularities do exist.

The lines in the second hydrogen spectrum may be divided into groups G_1, G_2, G_3, ..., G_n in such a manner that each line in one group corresponds with a line in each of the other groups. The reciprocal value of the wave-lengths of homologous lines $1/\lambda_1$, $1/\lambda_2$, $1/\lambda_3$, ..., $1/\lambda_n$ are found to be in the proportions to one another of the numbers $1 - \frac{4}{3^2}$, $1 - \frac{4}{4^2}$, $1 - \frac{4}{5^2}$, ..., $1 - \frac{4}{(n+2)^2}$. Of these groups there would appear to be at least 14, there being a necessary limit to their number as there is to that of the particles which transfer these different vibrations to the ether. H. C.

Theory of Secondary Batteries. By F. Streintz (*Ann. Phys. Chem.* [2], **46**, 449—463).—The author proves by measurements of the E.M.F. the presence of hydrated peroxide of lead as a secondary product on the plates of secondary elements, and considers that its formation is accompanied by a diminution of the E.M.F. of the element on charging, and its destruction by a corresponding increase on discharging.

Experiments were made to ascertain the dependence of the E.M.F. on the concentration of the acid in the cells. If the E.M.F. (E) is expressed in volts and the strength of acid (z) in grams H_2SO_4 per litre of solution, the following relation holds good for the ordinary temperature:—

$$E_z = 1{\cdot}850 + 0{\cdot}00057z,$$

or if s is the specific gravity of the solution and s_0 that of water at the temperature of experiment, then

$$E_s = 1{\cdot}850 + 0{\cdot}917\,(s - s_0).$$

The temperature coefficient of the E.M.F. was always found to be positive. Measurements were made at every fifth degree between 10° and 70°. The following are the coefficients for various values of the E.M.F:—

E.	$\frac{dE}{dT}10^6$.
1·9223	140
1·9828	228
2·0031	335
2·0084	285
2·0105	255
2·0779	130
2·2070	73

J. W.

Alteration of the Conductivity of a Solution by the Addition of a Small Quantity of a Non-Electrolyte. By R. J. Holland (*Ber.*, **25**, 2726—2727).—The author's work differs from that of Arrhenius (this vol., p. 1038) in that the non-electrolytes employed (benzene, toluene, xylene, and turpentine oil) were none of them solvents of the salts examined; purified methyl alcohol, dried by distillation with anhydrous copper sulphate, was the solvent used, solutions of 1/100, 1/1000, and 1/2000 normal concentrations being investigated with successive additions of 5, 10, 15, and 20 per cent. by volume of the non-electrolyte. The following are the general results with lithium, sodium, and potassium nitrate:—(1) The reduction of the conductivity by the addition of a non-electrolyte is proportional to the amount of the latter added; (2) the reduction of the conductivity varies according to the nature of the dissolved salt and that of the non-electrolyte; (3) the graphic representations of the molecular conductivities are straight lines. A. R. L.

Expansion of Water by Heat. By C. Puschl (*Monatsh.*, **13**, 440—449).—The author discusses the effect of pressure on the expansion by heat of water. Making use of Amagat's determinations, he shows that at high pressures (3000 atmos.) the expansion for each degree of temperature reaches a maximum as the temperature rises, and then begins to fall. H. C.

Stochiometry of Solutions. By G. Jäger (*Monatsh.*, **13**, 483—497).—In a former paper, the author has shown that the heat of vaporisation of a solution

$$r' = r[1 + (\kappa - \lambda)q] = r\left[1 + \frac{b\kappa}{r}\,q\right],$$

where r is the heat of vaporisation of the solvent, q the number of gram-molecules of dissolved substance in 1 litre of the solution, κ and λ constants, and b that portion of the heat of vaporisation which is necessary to overcome capillary forces. It is here shown that r' is also equal to $r + 2Av(d - d')$ where A is the mechanical equivalent of heat, d and d' the vapour pressure of the pure solvent and the solution, and v the volume of the solution. A number of interesting relationships are thus established between various properties of solutions.

It is also shown that the heat of fusion of a solution is smaller than that of the pure solvent, the difference being proportional to

the number of molecules of dissolved substance present in unit volume of the solvent. H. C.

Heat of Formation of Permolybdic Acid. By E. PÉCHARD (*Compt. rend.*, **115**, 227—229).—The direct neutralisation of permolybdic acid by sodium hydroxide develops +24·2 Cal., and by potassium hydroxide +24·0 Cal. The action of sulphuric acid on sodium permolybdate develops +6·9 Cal., and the result is the same whether the sulphuric acid is added all at once or in successive portions. The whole of the molybdic acid is not displaced, but a very acid molybdate is formed, its formation corresponding with 0·6 Cal.

The action of hydrogen peroxide on a mixture of sodium molybdate with sulphuric acid in molecular proportion develops +5·4 Cal., a quantity which may be regarded as the sum of the heat developed by the decomposition of the hydrogen peroxide and that absorbed by the formation of the permolybdate. It follows that the formation of the permolybdate absorbs −16·2 Cal.

The direct neutralisation of permolybdic acid develops with sodium hydroxide +11·2 Cal., and with potassium hydroxide +11·1 Cal. It follows that permolybdic acid will displace carbonic acid, but is itself displaced by the strong acids. The action of alkaline hydroxides on the permolybdates, with production of molybdates, gives for the heat of formation of permolybdic acid from molybdic acid −15·9 Cal., a number almost identical with that obtained by the action of hydrogen peroxide. The energy necessary for the formation of the permolybdic acid is derived from the decomposition of the hydrogen peroxide. C. H. B.

Molecular Volumes of Dissolved Substances. By J. TRAUBE (*Ber.*, **25**, 2524—2533).—The author has compared the molecular volumes of a large number of salts in aqueous solution as found by different investigators with the degree of electrolytic dissociation or "ionisation" of the salts, and finds that a very close relation exists between the two (compare Schmidt, Abstr., 1890, 844). To the objection of Ostwald that the numbers cannot simply represent molecular volumes of the dissolved substances, inasmuch as they are in certain cases negative, the author replies that in all such cases the salts contain water of crystallisation, and that when allowance is made for the contraction of the latter, the negative value disappears, and numbers are obtained which correspond with those of the anhydrous salts. H. G. C.

Permeability of Precipitated Membranes. By G. TAMMANN (*Zeit. physikal. Chem.*, **10**, 255—264).—Traube was of opinion that precipitated membranes were of the nature of molecular sieves, which let small molecules pass through them, but stopped large molecules. Ostwald (Abstr., 1890, 1354) developed this idea of Traube's for salts, and stated that membranes might be permeable, not for salt molecules as such, but for particular ions. Salts, of which both ions

could pass the membrane, would pass through as a whole; whilst if one of the ions were stopped, the salt could not pass at all.

The author has put these ideas to experimental proof. First of all, he took three membranes (tannate of gelatin, zinc ferrocyanide, and copper ferrocyanide) and determined their permeability to 17 different dye-stuffs (salts and acids) in aqueous solution. If the molecular sieve theory is correct, the order of permeability of the three membranes ought to be the same for all the dissolved substances. This he found not to be the case.

Acids diffuse through membranes of copper ferrocyanide in the order of their strength, that is, of their degree of dissociation into ions. This would indicate that it is principally the ions which pass the membrane, and not the undissociated acid. The following are some of the numbers obtained:—

Hydrochloric acid	9·0
Trichloracetic acid	6·6
Monochloracetic acid	3·3
Acetic acid	2·6

Experiments were made with a large number of salt solutions in respect of their power to pass through different membranes. The chlorides, bromides, and nitrates of potassium, ammonium, sodium, and lithium pass easily through copper ferrocyanide membranes. The corresponding sulphates diffuse with greater difficulty. The membrane is impervious to calcium and magnesium salts, but allows chlorides and bromides of barium and strontium to pass. Succinic, tartaric, citric, and isobutyric acids penetrate the membrane, but their potassium salts do not. These examples are sufficient to show that Traube's and Ostwald's views are untenable without modification.

The author inclines to the opinion that the process of passage through the membrane may be one of solution, as all the semi-permeable membranes with which we are acquainted are strongly hydrated. J. W.

Solubility Curves of Pairs of Salts. By H. W. B. Roozeboom (*Zeit. physikal. Chem.*, **10**, 145—164).—In this paper, the author discusses the solubility relations of pairs of salts which are capable of forming a double salt with each other as well as mixed crystals, and has examined in particular the solubility in water of mixtures containing ferric chloride and ammonium chloride in various proportions (compare this vol., p. 1048). He tabulates his results so that the numbers of molecules of ammonium chloride dissolved from the mixtures by 100 mols. of water appear as abscissæ, and the corresponding numbers for ferric chloride as ordinates. The solubility of the pair Fe_2Cl_6 : NH_4Cl at 15° is expressed in this way by an isotherm which consists of three curves cutting in pairs.

The first curve is for solutions which are in equilibrium with the hydrate $Fe_2Cl_6,12H_2O$, and runs between the limits

$$\left.\begin{array}{rl} 9{\cdot}30 \text{ to } 9{\cdot}93 & \text{mols. } FeCl_3 \\ \text{and} \quad 0 \text{ to } 1{\cdot}36 & \text{mols. } NH_4Cl \end{array}\right\} \text{to 100 mols. } H_2O.$$

The second curve gives the composition of the solutions in equilibrium with the double salt $4NH_4Cl,Fe_2Cl_6,2H_2O$.

Its limits are—

$$\left.\begin{array}{r} 9{\cdot}93 \text{ to } 6{\cdot}8 \text{ mols. } FeCl_3 \\ \text{and } 1{\cdot}36 \text{ to } 7{\cdot}8 \text{ mols. } NH_4Cl \end{array}\right\} \text{to 100 mols. } H_2O.$$

The third curve is for solutions which can exist in presence of mixed crystals (containing from 7·3 down to 0 per cent. of ferric chloride). It runs between the limits

$$\left.\begin{array}{r} 6{\cdot}8 \text{ to } \quad 0 \text{ mols. } FeCl_3 \\ \text{and } 7{\cdot}8 \text{ to } 11{\cdot}88 \text{ mols. } NH_4Cl \end{array}\right\} \text{to 100 mols. } H_2O.$$

The solution at the point of intersection of the two first curves is stable in presence of the hydrated ferric chloride and the double salt: that at the intersection of the second and third curves can exist in presence of the double salt and the mixed crystals containing the maximum amount of iron. The composition of the solutions at these points is independent of the quantity of the two solid phases. Whilst, however, the solution at the first intersection is not further altered by any addition of ferric chloride, or by the addition of ammonium chloride up to the point where all the solid ferric chloride is converted into the double salt, the solution at the second intersection is changed by the addition of one or other component, for each of these transforms one solid phase into the other.

The curve for the double salt shows that this salt cannot be dissolved without undergoing decomposition.

The mixed crystals contain the ferric chloride as Fe_2Cl_6 with 7 to 8 mols. H_2O; but whether as an isotropic or æolotropic admixture remains undecided. The relation between the quantity of iron in the mixed crystals and that in the solution is not well known.

The author enumerates various cases of solubility isotherms for salt pairs of different types. These all consist of one or more curves cutting each other in pairs. He also shows for these cases how the mixed solutions are changed by the addition of one or other solid component. J. W.

Solubility of Double Compounds. (Part II.) By R. Behrend (*Zeit. physikal. Chem.*, **10**, 265—283; compare this vol., p. 1047).—In this paper, the solubility relations of the compound which phenanthrene forms with picric acid are investigated for alcoholic solutions. The method was to dissolve the picrate (alone or with excess of phenanthrene or of picric acid) in warm, absolute alcohol, allow it to remain for a week at the ordinary temperature, kept constant as far as possible, and then estimate what had remained in solution as follows:—A weighed quantity of the solution was taken, and the alcohol driven off by a current of air at 60°. The residue was weighed, the picric acid in it determined by titration, and the phenanthrene by difference.

The results show that the picrate in saturated alcoholic solution at 12° is decomposed to the extent of almost 90 per cent. Considerable divergencies from the calculated numbers appear when a large excess

of phenanthrene is added. These the author shows to be due to the formation of complex (probably triple) molecules of phenanthrene in concentrated alcoholic solution. This conclusion is confirmed by observations of the boiling points of alcoholic anthracene solutions. In a 12 per cent. solution, the molecular weight is found to be 27 per cent. too high.

The author recalculates some of Beckmann's numbers for the molecular weights of substances in alcoholic solution on various assumptions as to the nature of the complex molecules formed. J. W.

Transportation of Solids in a Vacuum by the Vapours of Metals. By H. N. Morse and J. White, Jun. (*Amer. Chem. J.*, **14**, 314—315; compare Abstr., 1889, 775; 1891, 643).—The action is merely mechanical; barium carbonate and powdered porcelain are transported with equal facility and without change of composition, and porous plugs of asbestos allow the metallic vapours to pass, but stop all the solids. The explanation advanced previously by the authors, ascribing the result to dissociation, was erroneous.

The authors have also re-examined the gas given off on heating the oxides of zinc, cadmium, and magnesium in a vacuum with their respective metals. It is found to be pure nitric oxide, and is derived from some nitrate present in the oxide used. W. T.

Bunsen Burner for Spirit. By G. Barthel (*Ber.*, **25**, 2646—2648).—The burner consists of a thick-walled tube, fastened into an iron foot. The tube is divided horizontally into two parts. The lower part is filled with a metal network, and serves to vaporise the spirit. Just above the division are air holes, similar to those in an ordinary Bunsen burner. The spirit is introduced from a vessel about 1 metre above the burner, through a tube running into the foot of the burner, and the supply is regulated by a screw-tap just below the air-holes. A piece of wire gauze in the upper part of the tube causes the flame to burn steadily.

The temperature is higher than that obtained by an ordinary Bunsen burner. 1 litre of water can be heated from 15° to 100° in $7\frac{3}{4}$ minutes, with the consumption of 26 grams of spirit.

A drawing of the apparatus is given. E. C. R.

Simple Apparatus for Evaporating under Reduced Pressure. By C. Schulze and B. Tollens (*Annalen*, **271**, 46—48).—For the rapid evaporation of solutions of substances which readily undergo decomposition, the authors describe an apparatus similar in principle to that recently recommended by Yaryan for use in the extraction of sugar on the large scale.

The apparatus consists of a copper worm, immersed in boiling water, and closed at the top with an india-rubber cork through which passes a moderately wide glass tube; into the wide glass tube is fitted an india-rubber cork, through which passes a narrower glass tube provided with a stopcock, the uppermost portion of the narrow glass tube being bent at a right angle and connected with a glass tube which dips into a vesssl containing the solution to be evaporated.

The bottom of the copper worm is connected with one limb of a three-way, bulbed tube; of the other limbs, one passes directly downwards through an india-rubber cork into a closed flask-shaped vessel, whilst the other passes upwards, and, after bending over, is connected with a condenser. The lower end of the condenser fits air-tight into a flask which is connected with a water-pump, so that the whole of the apparatus is constantly exhausted. By opening the stopcock at the top of the copper worm, the solution to be evaporated is drawn into the apparatus, its flow being regulated at will; evaporation then takes place in the worm, the concentrated liquid falling into the flask-shaped receiver, whilst the water or other vapour passes onwards into the condenser. The flask-shaped receiver is provided with a lateral tubulus, closed with an india-rubber cork, through which passes a glass siphon tube; when a sufficient quantity of the concentrated solution has collected in the receiver, air is admitted into the apparatus, and the liquid is drawn off through the siphon.

Inorganic Chemistry.

Compounds of Chlorine with Iodine. By W. Stortenbeker (*Zeit. physikal. Chem.*, **10**, 183—202).—Calorimetric observations on the chlorides of iodine, made by the author by means of a Berthelot calorimeter, lead to the following results:—

	Per gram.	Per gram-molecule.
Specific heat of liquid ICl	0·158	—
„ ICl_α (m. p. 27·2°).	0·083	—
„ ICl_β (m. p. 13·9°).	*ca.* 0·085	—
Heat of fusion of ICl_α	−16·42 cal.	−2658 cal.
„ ICl_β	−14·0 „	−2267 „
Heat of transformation of ICl_β into ICl_α	1·25 „	203 „

The depression of the freezing point of glacial acetic acid by the chlorides gives numbers corresponding with the formula ICl for the monochloride and $ICl_3/2$ for the trichloride. There may nevertheless be dissociation of the monochloride in solution into chlorine and iodine, for the number of molecules on the two sides of the equation $2ICl = I_2 + Cl_2$ is the same. The trichloride evidently dissociates in solution into $ICl + Cl_2$, the molecular depression decreasing as the concentration increases. These results agree with those obtained from vapour density determinations.

The author attempted other freezing point experiments by using the monochloride itself as solvent, the melting point of which is depressed by an excess of chlorine or excess of iodine. When there is excess of chlorine present, the solution very probably contains tri-

chloride. But as the trichloride tends to dissociate into monochloride and chlorine, we have here a case in which the solvent is one of the dissociation products of the dissolved substance. Raoult's law does not apply directly to such a case. The author discusses the subject from the thermodynamical point of view, and develops the necessary equations. J. W.

Iodine Trichloride. By E. Tavel and A. Tschirch (*Arch. Pharm.*, **230**, 331—341).—Iodine trichloride is decomposed by water with formation of the monochloride, hydrogen chloride, and iodic acid. It is thus a matter of indifference whether the trichloride or the monochloride be employed as an antiseptic. The action of the trichloride (that is, the monochloride) solution on *Staphylococcus citreus*, green pus, and the anthrax bacillus is very energetic, rivalling that of chlorine. The hydrochloric and iodic acids play only a subsidiary part; the antiseptic action of the latter is stronger than that of the former for *Staphylococcus citreus* and green pus.

A. G. B.

Iodic Acid and its Salts. By A. Ditte (*Ann. Chim. Phys.* [6], **21**, 145—188).—The author describes the preparation and properties of the iodates of most of the common metals, and of a number of organic bases. Many of the metallic salts have been previously described by Rammelsberg, Millon, Marignac, and others; the organic salts crystallise readily. F. S. K.

Atomic Weight of Oxygen. By A. Leduc (*Compt. rend.*, **115**, 311—313).—The calculations are based entirely on the sp. gr. of electrolytic gas, hydrogen, and oxygen (compare Abstr., 1891, 1416). Special precautions were taken to ensure the purity of the electrolytic gas, which was made by passing a current of 5 ampères between platinum electrodes in 30 per cent. aqueous potash for several days under constant conditions of temperature and pressure.

The sp. gr. of electrolytic gas referred to air was thus found to be 0·41423; with a maximum error of 1 in 10,000. Taking the sp. gr. of hydrogen as 0·06947, and that of oxygen as 1·10503, electrolytic gas contains 66·708 per cent. of hydrogen and 33·292 per cent. of oxygen by volume, so that the ratio of hydrogen to oxygen is 2·0037, and the atomic volume of oxygen 1·9963. The atomic weight of oxygen calculated from these data

$$\left(= \frac{\text{vol. per cent. of oxygen} \times \text{sp. gr. of oxygen}}{\text{vol. per cent. of hydrogen} \times \text{sp. gr of hydrogen}}\right)$$

is 15·877, a number agreeing closely with the value 15·882 previously obtained by the author by a synthetical method (this vol., p. 1271). The value 15·88 is considered the most probable. The molecular weight of water vapour is then 17·88, giving a sp. gr. of 0·6212, taking that of hydrogen as a basis, or 0·6221, taking that of oxygen as a basis. The latter is probably the more correct, as the compressibility of oxygen is approximately equal to that of air.

Jn. W.

Insoluble Sulphur. By W. Schmitz-Dumont (*Ber.*, **25**, 2659—2661).—Bellamy (*Compt. rend.*, **91**, 330) has stated that sulphur insoluble in carbon bisulphide differs from the soluble modification in the following particulars :—If sodium thiosulphate is being prepared from the neutral sulphite and the insoluble modification of sulphur, then : (1) hydrogen sulphide is formed during the boiling ; (2) the hot filtered solution becomes milky after a time, and a notable quantity of sulphur separates out with the thiosulphate ; (3) the insoluble modification is dissolved in greater quantity than the soluble modification.

The author, however, was unable to detect any difference in chemical behaviour between the soluble and insoluble modifications. Quantitative experiments showed that both modifications evolve the same amount of hydrogen sulphide when boiled with sodium sulphite, and also when boiled with water. On crystallising the thiosulphate, no precipitation of sulphur was observed, and on allowing the solution to remain, it gradually became milky, just as a solution of hydrogen sulphide does. Also both modifications are equally soluble in the sulphite ; but the insoluble modification dissolves somewhat more quickly. E. C. R.

Formation of Sulphuric Acid and Ammonium Sulphate by Burning Coal Gas. By E. Přiwoznik (*Ber.*, **25**, 2676—2680).—From the following experiments, the author concludes that free sulphuric acid is not given off by burning coal gas. If a platinum dish containing about 0·5 litre of water is placed over a Bunsen flame so that only the point of the flame is in contact with the dish, the cold dish becomes covered with dew, which gradually disappears without leaving a deposit of sulphuric acid. After heating for half an hour, a small deposit of ammonium sulphate is formed. Again, if 5 litres of water free from ammonia is evaporated to a small bulk in a platinum dish over a Bunsen flame, and the residue then evaporated to dryness on the water-bath, a dry salt is obtained, which would not be the case if the liquid contained free sulphuric acid. When vessels of porcelain or enamelled iron are employed instead of platinum, ammonium sulphate is also formed, but the formation of a dew of sulphuric acid could not be detected.

The author suggests that the formation of sulphuric acid, so often noticed when platinum is employed, is due to the combination of sulphurous acid with oxygen condensed on the platinum. Thus, if a platinum dish heated to redness by means of a spirit lamp is held over a porcelain basin containing sulphurous acid, sulphuric acid is formed and may be detected by rinsing the platinum dish with water, acidifying the solution with hydrochloric acid, and adding barium chloride. E. C. R.

The Amides and Imides of Sulphuric Acid. By W. Traube (*Ber.*, **25**, 2472—2475).—If a solution of sulphuryl chloride in 15 to 20 times its volume of chloroform is saturated with dry ammonia, the product shaken with water until the precipitate has dissolved, and the aqueous solution boiled with lead or silver oxide until all

chlorine is removed, the filtered solution, when evaporated, leaves a viscid, hygroscopic syrup; this gives no precipitate with barium or platinum chloride, but is converted into ammonium sulphate by boiling with hydrochloric acid. It is possibly the neutral amide of sulphuric acid, $SO_2(NH_2)_2$; with mercuric nitrate, lead acetate, or ammoniacal silver nitrate, it gives precipitates from which hydrogen sulphide liberates the original substance. When heated, it loses ammonia; at a higher temperature, sulphurous anhydride is evolved. If the silver compound is heated (better with a little ammonium chloride) at 170—180° until no more ammonia is evolved, the silver salt of sulphimide, SO_2NAg, is formed; it crystallises from very dilute nitric acid in long needles, and dissolves readily in hot, sparingly in cold water. Its solution gives no precipitate with barium nitrate, even after the silver has been removed by means of hydrochloric acid. When heated, it leaves metallic silver, mixed with a little silver sulphate. C. F. B.

Action of Nitric Peroxide on Metals and Metallic Oxides; Nitro-metals. By P. Sabatier and J. B. Senderens (*Compt. rend.*, **115**, 236—239).—Nitric peroxide acts more readily than nitric oxide on metals and metallic oxides, and usually yields more highly oxidised products.

Manganous oxide at about 350° yields the sesquioxide; titanium sesquioxide at 300° yields titanic anhydride; brown tungsten dioxide becomes incandescent at 300°, and yields tungstic anhydride; black vanadium trioxide oxidises between 300° and 400°, and yields the brownish yellow pentoxide; cuprous oxide at 300° yields cupric oxide.

Aluminium foil is not appreciably oxidised at 500°; magnesium foil is oxidised only at a dull red heat, but at this temperature it burns with great energy; zinc oxidises regularly at 300°; lead oxidises slowly at 200°, and yields a white basic nitrate. Reduced iron oxidises with incandescence at about 350°, and yields ferric oxide; reduced cobalt burns brilliantly at the ordinary temperature, and yields the black oxide, Co_4O_5; reduced copper at 250° yields cupric oxide.

Nitro-metals.—Reduced copper absorbs nitric peroxide at the ordinary temperature with considerable development of heat, the mass becoming perceptibly warm, and when this development of heat ceases, a maroon-coloured product is obtained of the composition Cu_2NO_2. This compound reacts violently with water, and yields pure nitric oxide, a solution of cupric nitrate with a small quantity of nitrite, and a residue of metallic copper. When heated in pure and dry nitrogen, nitric peroxide is evolved, and a residue of partially oxidised copper is left. In the preparation of this compound, the nitric peroxide must be quite free from nitric acid, and this is secured by placing in the front part of the tube a layer of litharge followed by a layer of phosphoric anhydride.

If a current of nitric peroxide largely diluted with nitrogen is passed over reduced cobalt, the latter does not burn, but yields a black *nitro-cobalt*, Co_2NO_2, very similar in properties to the copper compound. C. H. B.

Hydroxylamine. By C. A. Lobry de Bruyn (*Rec. Trav. Chim.*, **11**, 18—49; compare this vol., p. 402).—Hydroxylamine hydrochloride dissolved in methyl alcohol is treated with sodium methoxide as previously described, and the greater portion of the alcohol, after separation of the sodium chloride, is distilled off at a pressure of 100 mm.; the residue is further distilled in small portions at a time under a pressure of 40 mm. as rapidly as possible, frothing being prevented by the addition of a little vaseline. So soon as solid hydroxylamine passes over, the receiver is changed for one cooled in iced water, especial care being taken to avoid contact of hydroxylamine with the air for any length of time at 60—70°, since under these circumstances it explodes violently. The crystalline hydroxylamine may be further purified by fractional crystallisation. From 1·2 kilos. of hydroxylamine hydrochloride, the author obtained 100 grams of crystalline hydroxylamine.

Solid hydroxylamine forms white, inodorous scales or hard needles, which melt at about 33·05°, but remain in a state of superfusion on cooling to 0°; it boils at 58°under a pressure of 22 mm.; when heated at 90—100°, it decomposes with evolution of gas, and detonates at a higher temperature. The crystals have a sp. gr. of 1·35 as determined by the method of suspension, using a mixture of chloroform and benzene; whilst in the liquid state, as taken by Westphal's balance and the pyknometer, the value 1·23 is obtained. Eykman determined the refractive index at 14° and 40° respectively as n_α = 1·44123 and 1·43359. Hydroxylamine may be titrated, using methyl-orange as an indicator. An elementary analysis by Dumas' method and determination of its molecular weight by Raoult's method indicate a molecular weight of 33. On exposure to air, the crystals liquefy, increase in weight, and volatilise completely. The pure substance is stable, but the presence of traces of free alkali, as in some glass bottles, causes it to decompose, and it is slowly oxidised on exposure to air, but the concentrated solutions are very stable. Heated at 90°, decomposition occurs, the temperature rises to 130°, and a violent explosion ensues, but at 40—45° it may be decanted without risk. In addition to the properties previously described (*loc. cit.*), methyl alcohol at 5° dissolves 35 per cent.; ethyl alcohol at 15°, 15 per cent.; and boiling dry ether 1·2 per cent., the latter solution depositing acicular crystals on cooling; ethyl acetate dissolves 1·6 per cent.

Hydroxylamine inflames in a current of dry chlorine; bromine and iodine, however, decompose it without flame, with formation of hydrobromic and hydriodic acids. Exposed to the air, solid hydroxylamine suffers oxidation; a white deposit is formed which contains both nitrous acid and ammonia, and when dry oxygen is passed through fused hydroxylamine, white fumes of nitrous acid are produced with but little liberation of heat. Sodium attacks hydroxylamine with production of flame, and when added to its solution in dry ether, hydrogen is evolved, and a voluminous, white, amorphous substance is formed; on exposure to air, this liquefies, develops heat, and intumesces with evolution of gas and formation of nitrous acid. A quantitative research on this reaction tends to the belief that a compound of hydroxylamine with sodium hydroxylaminate is formed, and that this

compound explodes spontaneously. Sulphur, phosphorus, and magnesium powder do not react with hydroxylamine, but warm zinc-dust reduces it with formation of ammonia and zinc oxide, an explosion occurring if notable quantities are involved.

Crystals of potassium permanganate, chromic acid, ammonium dichromate, potassium and sodium chromates placed in contact with hydroxylamine crystals produce decomposition with a white flame, but potassium and sodium dichromates cause a sharp, violent explosion.

The oxides and peroxides of the metals also induce decomposition, with production of flame, as do potassium chlorate, perchlorate, and bromate on the addition of a drop of sulphuric acid. Iodic anhydride attacks hydroxylamine when the latter is not in excess, with liberation of iodine, and hydroxylamine reduces sodium iodate to iodide, the reaction in each case being violent. Powdered silver nitrate is reduced by hydroxylamine to the metallic condition, and anhydrous cobalt sulphate to a brown, amorphous mass. Anhydrous copper sulphate inflames hydroxylamine, and the powdered hydrated salt is reduced, but the anhydrous sulphates of nickel, manganese, magnesium, and zinc are unaffected.

Hydroxylamine dissolves sodium and barium hydroxides, and a solution of the first named substance absorbs oxygen from the air with formation of nitrous acid, becoming gradually warmer and entering into a state of effervescence with evolution of steam and ammonia. Hydroxylamine reacts with hydrogen peroxide to form nitrous acid, and a strong solution of sodium hypobromite rapidly oxidises it. Phosphorus trichloride and pentachloride cause the ignition of hydroxylamine, and the addition of a chloroform solution of the trichloride to solid hydroxylamine suspended in that solvent, causes the formation of a voluminous, white, amorphous mass, which contains phosphorous acid, hydroxylamine, and chlorine.

Rapid currents of carbonic anhydride and carbonic oxide, of nitrous oxide, and of nitric oxide are without effect on melted hydroxylamine, but nitric peroxide is reduced thereby. Hydroxylamine dissolves gaseous ammonia freely, also carbonic anhydride and hydrogen sulphide, forming with the last two, thick liquids which do not solidify at $-10°$. Benzyl chloride, methyl iodide, and acetone react eagerly with hydroxylamine; the dinitrobenzenes are attacked, but nitrobenzene is not. A solution of hydroxylamine in methyl alcohol reduces silver nitrate, and forms a bluish violet precipitate with anhydrous copper sulphate dissolved in that solvent.

Together with Crismer (Abstr., 1890, 558), the author has mentioned the fact that hydroxylamine forms with some chlorides compounds analogous to their hydrated salts. In the present paper, he gives determinations of the solubilities of some salts and of ammonia in hydroxylamine.

In concluding, he discusses the validity of the formulæ proposed for hydroxylamine, and decides in favour of $NH_2{\cdot}OH$. T. G. N.

Boron Trisulphide. By H. Moissan (*Compt. rend.*, **115**, 203—208).—Boron trisulphide can be obtained in several ways:—(1.) By

the action of melted sulphur on boron iodide; even after heating at 240°, the product retains a small quantity of sulphur. (2.) By the action of sulphur vapour on amorphous boron; at 610° the boron becomes covered with a protecting layer of the sulphide, but at 1200°, if a very slow current of hydrogen is passed through the tube with the sulphur vapour, the boron sulphide sublimes. The product is yellow, and has a crystalline fracture, but contains a large excess of sulphur, the greater part, but not all, of which can be removed by distillation. This retention of sulphur is due to the existence of a boron pentasulphide. (3.) By the action of hydrogen sulphide on pure boron at a bright red heat; the product is crystalline, white, and very light, and is decomposed by water without any separation of sulphur. (4.) By the action of pure carbon bisulphide vapour on boron at a bright red heat; the product is white and crystalline. (5.) By the action of tin, antimony, or arsenic sulphide on amorphous boron at a red heat.

When condensed in a large receiver, boron sulphide forms white, slender needles, which are very unstable, and are decomposed by water with evolution of hydrogen sulphide and without separation of sulphur. It begins to melt at 310°, and passes through a pasty condition; sp. gr. about 1·55. It is insoluble in most solvents, but is slightly soluble in phosphorus trichloride, from which it crystallises in slender, colourless needles, and is still more soluble in sulphur chloride, from which it does not crystallise, probably in consequence of the formation of a new compound.

Hydrogen does not reduce boron sulphide between a dull red and a bright red heat. When thrown into chlorine, the sulphide burns with a green flame, forming boron and sulphur chlorides, and in presence of excess of chlorine these compounds yield a double compound of boron trichloride and sulphur tetrachloride, liquid at the ordinary temperature but solid at −23°. Bromine has no action on the sulphide at the ordinary temperature, but on heating, an energetic reaction takes place. Iodine has no reaction even at the softening point of glass. At a dull red heat in a current of oxygen, boron sulphide burns with a green flame, but the layer of oxide formed prevents the reaction from becoming complete. Sulphur dissolves in all proportions in fused boron sulphide, and cannot afterwards be entirely expelled by distillation. Nitrogen, phosphorus, carbon, and silicon are without action on the sulphide at a red heat, but sodium and potassium decompose it below dull redness with vivid incandescence, metallic sulphides and borides being formed. Magnesium behaves similarly, and yields magnesium sulphide and boron, but aluminium yields aluminium sulphide and aluminium boride. Reduced iron or silver, zinc, copper, or mercury gives no similar reaction.

Water decomposes boron trisulphide violently, and the reaction is expressed by Sabatier's equation, $B_2S_3 + 6H_2O = 2B(OH)_3 + 3H_2S$. Dry ammonia combines with boron sulphide with great development of heat, forming a yellow powder; this when heated yields a white residue which evolves ammonia on being treated with potassium hydroxide solution.

Boron trisulphide in nitric oxide at a red heat yields boric anhydride

and sulphur; in nitrogen peroxide, it yields boric anhydride and sulphuric anhydride. When thrown into nitric acid, oxidation takes place with incandescence. Bromine water converts it into boric and sulphuric acids. Hydrogen chloride at about 400° yields boron chloride and hydrogen sulphide; hydrogen iodide has no action even at 920°. Phosphorus, arsenic, and sulphur chlorides seem to form double compounds.

Organic compounds react energetically with boron sulphide, and, as a rule, yield hydrogen sulphide. Saturated hydrocarbons are without action. Terebenthene and amylene dissolve the sulphide in the cold with evolution of hydrogen sulphide. Methyl, ethyl, isobutyl, and amyl alcohols and the principal phenols behave similarly, and dissolve boron sulphide with evolution of hydrogen and without separation of sulphur. Acetic chloride at the ordinary temperature yields a volatile compound with a repulsive odour. Organic bases, and aniline in particular, form crystalline compounds with the sulphide at the ordinary temperature. Aldehydes also form crystalline compounds. Phenyl cyanide forms a crystalline compound which does not evolve hydrogen sulphide unless heated. C. H. B.

Boron Pentasulphide. By H. Moissan (*Compt. rend.*, **115**, 271—273).—*Boron pentasulphide*, B_2S_5, is a light, white, crystalline powder, which melts sharply at 390°, and has the sp. gr. 1·85. It is made by heating boron iodide (20 grams) with sulphur (rather less than 1 equiv.) in carbon bisulphide solution for 24 hours at 60°. The precipitated product is washed with carbon bisulphide to remove the iodine, but cannot be obtained in the pure state, as it forms a very sparingly soluble additive compound with the latter.

The pentasulphide is hydrolysed by water into boric acid, hydrogen sulphide, and sulphur, and resembles the trisulphide (preceding abstract) in its behaviour with alcohol, the excess of sulphur separating in the free state. It dissociates into the trisulphide and sulphur when heated to its melting point in a vacuum, and is decomposed in a similar manner when heated with mercury or silver, a sulphide of the metal being formed. It is converted by aqueous potash into potassium borate and polysulphide, and is acted on by chlorine at a low temperature with the formation of an unstable crystalline substance. Jn. W.

Artificial Corrosion of the Diamond. By W. Luzi (*Ber.*, **25**, 2470—2472).—Diamonds were corroded by heating them for half an hour in the melted matrix ("blue ground") in which they occur in South Africa. They were then found to have irregular or elliptical hollows on the surface, in one case so deep that the diamond was nearly bored through. At the same time the diamonds were usually blackened or covered with a red layer of iron oxide, and occasionally tiny black or dark-grey magnetic globules were observed in the hollows; these dissolved partly in hydrochloric acid with evolution of gas. Probably the process depends on a reduction of the magma at the expense of the carbon of the diamond. C. F. B.

Extraction of Rubidium and Cæsium Compounds from Carnallite. By W. Feit and K. Kubierschky (*Chem. Zeit.*, **16**, 335—339).—The authors' object was to obtain the rubidium and cæsium salts from carnallite by such operations as would not interfere with the usual process of working this mineral for its salts. This process may be briefly described as follows:—The coarsely-ground carnallite is dissolved in hot liquor, which has been obtained at a later stage in the working of a previous batch (see below), and the solution is poured off the residue into crystallising vats. The crystals are commercial potassium chloride; they are washed with cold water, and the washings (*decklaugen*) serve for dissolving a fresh batch of carnallite. The mother liquor from the potassium chloride crystals is evaporated, whereby sodium chloride (*bühnensalz*) is separated, and run into crystallising vats, where "artificial carnallite" crystallises; this is worked up again. The second mother liquor (*endlauge*) is used for the production of magnesium chloride and bromine. It will be seen that the products are (1) residue, (2) potassium chloride, (3) *decklaugen*, (4) artificial carnallite, and (5) *endlauge*. It was found that, notwithstanding the great solubility of rubidium and cæsium salts, the *endlauge* contains but little of them, and that they are distributed through the last four of the above mentioned products. Their presence in the artificial carnallite is to be explained similarly to the presence of potassium chloride in this product, which is due to the fact that, so long as the liquor contains less than 300 grams of magnesium chloride per litre, nearly pure potassium chloride crystallises; after this concentration has been reached, however, the double chloride of potassium and magnesium separates. Their presence in the commercial potassium chloride can be explained by the fact that, although a dilute solution of magnesium chloride at 20° can dissolve much more rubidium or cæsium chloride than of potassium chloride, the quantity of the former chlorides, soluble in stronger solution of the magnesium salt, falls off much more rapidly than is the case with potassium chloride, until it is found that in strong solutions of magnesium chloride the potassium salt is the more soluble. Thus, a solution of magnesium chloride, containing 50 grams per litre, dissolved 245 grams per litre of potassium chloride and 625 grams per litre of rubidium chloride; one containing 250 grams per litre dissolved 73 grams of potassium chloride and 168 grams of rubidium chloride; whilst one containing 400 grams of magnesium chloride dissolved 30 grams of potassium chloride and 6 grams of rubidium chloride. These observations are in accordance with the known fact that the double salts of rubidium and cæsium are less soluble than those of potassium; they also indicate that the *endlauge*, which contains some 360 grams of magnesium chloride per litre, should retain some 15 grams of rubidium chloride. This is certainly not the case; but the same applies to potassium chloride, which should be present to the extent of 34 grams per litre, whereas only 10 grams are found. The presence of magnesium sulphate and sodium chloride in the *endlauge* must be held to modify the conditions, even less of the chlorides in question being then soluble.

The existence of *rubidium carnallite*, $RbCl,MgCl_2,6H_2O$, being thus

indicated, the authors prepared the salt. It differs from potassium carnallite in that it crystallises unchanged from water, and is not decomposed by a small quantity of water. As might be expected, by analogy with the insolubility of rubidium and cæsium alums in a saturated solution of potassium alum, rubidium and cæsium carnallites proved much less soluble in magnesium chloride solution when potassium chloride was present. Thus, a solution containing 330 grams of magnesium chloride and 31 grams of potassium chloride per litre only dissolved 1·5 grams of rubidium chloride per litre (compare above).

It will be apparent, from what has been written, that the artificial carnallite must be regarded as containing the bulk of the rubidium and cæsium chlorides. By an elaborate series of crystallisations, based on the above observations, the authors succeeded in obtaining a carnallite rich in rubidium chloride; this was decomposed by hot sodium carbonate, the heat being continued until all ammonia (which also concentrates itself in the artificial carnallite) was expelled. By further recrystallisations from the filtrate, a potassium chloride, rich in rubidium chloride, was obtained; estimations of the rubidium in this, by the platinic chloride method, indicated that the original artificial carnallite contained 0·025—0·030 per cent. of rubidium chloride. A much better result was obtained by dissolving artificial carnallite in hot water, and adding more of the salt, until the liquor above the separated salts had reached the sp. gr. 33° B. The crystals then consisted of potassium chloride and carnallite, and showed, by analysis, the presence of 1·5 per cent. of rubidium chloride. From 12,000 kilos. of artificial carnallite, 1200 kilos. of this mixture were obtained. 1000 kilos. of this were further concentrated as follows:—Some of the salt was dissolved to saturation in hot water and crystallised; the mother liquor was boiled, again saturated with the salts, and again crystallised. More salts were dissolved in this second mother liquor, until its sp. gr. was 30° B., sodium chloride being thus separated; it was then evaporated to 31° B., whereby more sodium chloride and potassium chloride were eliminated. The clear liquor was finally crystallised, and 110 kilos. of a mixture of salts, containing 9·5 per cent. of rubidium chloride, were obtained. No crystallisation method will serve to enrich this product, because the isomorphism of potassium and rubidium salts causes them to crystallise in varying proportions at the concentration of such a mixture. To obtain pure rubidium chloride, a saturated solution of the 9·5 per cent. salt was precipitated, with constant stirring, by stannic chloride. (The presence of concentrated hydrochloric acid, as usually advised, was found to be unnecessary in the presence of so much magnesium chloride. The authors applied this method with success for concentrating the rubidium chloride prior to estimating it with platinic chloride.) The rubidium stannichloride was dissolved in a little water and reprecipitated by the addition of an equal volume of strong hydrochloric acid, this process being repeated six or seven times, until the line Kα disappeared from the spectrum. The double chloride was then heated gently (to avoid the formation of stannates) with the calculated quantity of sodium carbonate, to convert the tin into stannic oxide.

The solution of the ignited mass contained chlorides of rubidium, cæsium, and sodium, and from it the rubidium was precipitated by sodium hydrogen tartrate; after several recrystallisations, pure rubidium hydrogen tartrate was obtained. The cæsium was separated from the concentrated mother liquors by stannic chloride; the double chloride was purified by several reprecipitations by concentrated hydrochloric acid, and decomposed by hydrogen sulphide; the cæsium chloride was finally precipitated with antimony trichloride, whereby, after two crystallisations from dilute hydrochloric acid, the pure salt $SbCl_3,6CsCl$ was obtained (Abstr., 1874, 816).

The isolation of the rubidium and cæsium can also be effected by dissolving 1 kilo. of the 9·5 per cent. salt in 2·5 litres of hot water, filtering, and adding a solution of 800 grams of aluminium sulphate in 800 c.c. of water. On cooling to 20°, rubidium and potassium alums crystallise; these can be separated by dissolving the mixture in $1\frac{1}{2}$ times its weight of hot water, and cooling to 40°. This is repeated until the lines Kα and Rbγ are about equally strong in the spectrum. An equal weight of water is then used, and the cooling carried to 35°. In all, seven to eight recrystallisations are necessary. The cæsium alum remains with the rubidium alum, and is separated by fractional crystallisation of the mixture from a little water at 60°; the cæsium alum crystallises in the first fraction, and is purified by recrystallisation from 20 times its weight of water. Precipitation with antimony trichloride may also be used. The conversion of the alums into other salts may be effected by well-known methods.

Redetermination of the Atomic Weight of Cadmium. By H. N. Morse and H. C. Jones (*Amer. Chem. J.*, **14**, 261—273).—The authors have employed the method of converting the metal into nitrate, and, subsequently, into oxide, as used in the case of zinc (Morse and Burton, Abstr., 1888, 1247), and in the case of magnesium (Burton and Vorce, Abstr., 1890, 850). Cadmium, in the form of powder, was heated for a long time in hydrogen which had been purified by washing with acid and alkaline solutions of potassium permanganate, and then distilled, as in the preparation of pure zinc. The sixth distillate was examined spectroscopically by Rowland, and found to be free from all impurities which can be thus detected. This product was dissolved in nitric acid (purified as in the zinc determination), and, subsequently, treated in the same manner as with zinc, the porcelain crucible employed being always weighed against a second tared crucible, subjected to the same treatment as itself.

As cadmium oxide attacks porcelain vigorously at the temperature of the muffle-furnace, the final heating was carried out in a bath consisting of a nickel crucible, heated for two or three hours over the blast-lamp. Any possible contact of the oxide with the reducing gases of the flame was avoided by forcing the nickel crucible tightly into a hole in an asbestos board. The completeness of the decomposition was ascertained by testing the oxide with pure potassium iodide and hydrochloric acid.

Ten successive determinations gave results varying between 112·053 and 112·086 (O = 16), mean 112·0705, from total oxide and

total cadmium, 112·0706. This result agrees best with those of Von Hauer (mean of 9, 111·940) and Lenssen (mean of 3, 112·067), but differs considerably from Partridge's results (Abstr., 1891, 390 and 399); hence the authors have also carried out a series of determinations by the conversion of the oxalate into oxide, to compare with those Partridge obtained by that method. The mean of five determinations (varying from 111·981 to 112·051) made in this way was 112·025, as compared with the number 111·809 obtained by Partridge, and 112·036 by Lenssen (O = 16 and C = 12·001).

The number 112·0706 is regarded as more accurate than the number 112·025, as, in the oxalate method, the atomic weight of carbon is involved, the oxalate is strongly hygroscopic, and there is danger of loss by reduction to, and volatilisation of, metal.

W. T.

Crystals of Metallic Cadmium. By G. H. Williams (*Amer. Chem. J.*, **14**, 273—276).—Cadmium is hexagonal and holohedral, and thus, along with zinc and magnesium, confirms the suggestion of Brögger and Flinck, derived from the analogy of these metals with beryllium (*Zeit. f. Kryst.*, **9**, 1884, 236).

The cadmium crystals were produced by distillation in a vacuum. Polyhedral aggregates were abundant and large, but crystals suitable for measurement were very small. The largest individuals were barrel-shaped, like those of zinc, and resembled piles of basal plates; their side planes were often uneven and bent. The most minute crystals show pyramidal faces of comparative perfection, which, however, yield compound reflections.

Cadmium crystals show only the three faces 0P, P, and ∞P, and have a tendency to hemimorphic development. The axial ratio is $a : c :: 1 : 1{\cdot}6554$.

A comparison between the axial ratios of the four rhombohedral and four holohedral hexagonal elements throws zinc into the rhombohedral division with bismuth, antimony, tellurium, and arsenic, rather than with beryllium, magnesium, and cadmium. Zinc crystals occasionally show a rhombohedral alternation of the faces of certain pyramids, but otherwise appear to be holohedral.

W. T.

Mercury Phosphide. By Granger (*Compt. rend.*, **115**, 229—230).—Mercury and phosphorus are without action on one another, even when heated together in sealed tubes. If, however, mercury and phosphorus iodide are heated together in sealed tubes at 275—300° for 10 hours, mercuric iodide and phosphide are obtained. The iodide is removed by treatment with potassium iodide solution, and the phosphide is left in brilliant crystals with a metallic lustre. They have the composition Hg_3P_2, and belong to the hexagonal system, showing the faces p and a', combined with a hexagonal prism. The crystals are red by transmitted light and yield a brown powder.

Mercuric phosphide is stable at the ordinary temperature, but splits up into phosphorus and mercury when heated. When heated in air, it burns, and when finely powdered and mixed with potassium chlorate, it detonates under the hammer. If thrown into chlorine, it burns

at the ordinary temperature. Nitric and hydrochloric acids are without action separately, but aqua regia dissolves it readily.

Mercury phosphide can also be obtained by passing phosphorus iodide over mercury heated at about 250°, but the separation of the two products is then difficult and tedious. C. H. B.

Mineralising Influence of Ammonium Sulphate. By T. Klobb (*Compt. rend.*, **115**, 230—232).—When lead sulphate is heated with excess of ammonium sulphate until the whole of the latter is just volatilised, a greyish, microcrystalline powder is obtained, consisting of short, transparent prisms resembling those of anglesite; sp. gr. = 6·28. They have the composition of normal lead sulphate.

As a rule, the ammonium sulphate seems to form intermediate double salts. With copper sulphate, this is especially distinct, and the products obtained at different temperatures are (1) $2CuSO_4,(NH_4)_2SO_4$; (2) $CuSO_4$; (3) $2CuO,SO_3$; (4) CuO. The first forms pale green prisms; sp. gr. about 2·85. It is very soluble in water, and when exposed to air rapidly becomes blue and opaque, 42 per cent. of water being absorbed at 20° in 42 days. The second forms distinct prismatic crystals of sp. gr. 3·78; they are less hygroscopic than the double salt, but gradually absorb water when exposed to the air. The basic sulphate is opaque and brownish-yellow, but retains the form of the normal sulphate; sp. gr. = 4·21. The oxide obtained by strongly heating the basic sulphate is crystalline and non-hygroscopic; sp. gr. = 6·36. C. H. B.

Micrographic Analyses of Alloys. By G. Guillemin (*Compt. rend.*, **115**, 232—234).—When the polished surface of an alloy is treated with dilute cold nitric acid, or with sulphuric acid of 10 per cent., under the influence of a feeble electric current (2 volts and 1 ampère), and the corroded surface is examined under a microscope, figures are obtained which vary with different alloys, but are invariably the same for the same alloy. These images can be photographed; they consist of more or less tortuous furrows, separated by ridges of unattacked metal. There seems little doubt that the alloys at the moment of solidification undergo partial liquation, and separate into several simple alloys of definite composition.

The examination of these surfaces makes it possible to classify ordinary alloys into a limited number of groups. In the case of bronze and brass, for example, it is possible to distinguish bronzes with a tin base, phosphor bronzes, brass containing less than 37 per cent. of zinc, Muntz metal, and brass containing more than 37 per cent. of zinc, aluminium bronze, aluminium brass, Delta metal, Roman bronze, &c. In white alloys, the presence of lead can be recognised, and its quantity estimated with close approximation. Ingots of copper from the same melting, but different stages of casting, show clearly the different degrees of refining. The presence of very small quantities of aluminium or phosphorus in brass or bronze can be detected with certainty. The presence of 4 per cent. or more of zinc in a tin bronze seems to mask the micrographic character of the phosphorus.

With one and the same alloy, the figures indicate differences in the mode of casting and cooling, and in mechanical treatment.

C. H. B.

Earths of the Cerium and Yttrium Groups. By A. Bettendorff (*Annalen*, **270**, 376—383).—In a previous paper (Abstr., 1891, 984), the author described the separation of the samarium earths from those of terbium and gadolinium; he has now investigated the solution containing the yellowish-red earth, RO = 119·96.

When the concentrated solution of the nitrates of the terbium and gadolinium earths is fractionally precipitated with ammonia, and the operation repeated systematically, there is finally obtained a dark brown earth, RO = 122, which consists for the most part of terbium earth; the relatively more basic oxide, RO = 119·68, has only a slight yellow tinge, and consists principally of the gadolinium earth. A spectroscopic examination of the concentrated solutions of the nitrates of these two oxides showed that the whole of the samarium originally present in the mixture, RO = 119·96, had accumulated in the gadolinium earth, the terbium earth being quite free from samarium. For the further purification of the gadolinium earth, it is submitted to systematic fractional precipitation with dilute ammonia; the samarium which accumulates in the first fractions is then removed by precipitating a concentrated solution of the nitrates with potassium sulphate, in the manner already described (*loc. cit.*). The first fractions of the gadolinium earth, purified in this way, were found to have an equivalent RO = 119·9; the last fractions were found to have an equivalent RO = 120·09—120·16, and gave on spectroscopic examination only indications of the absorption lines of the samarium earths, the indications being somewhat more decided in the first fractions. The combined fractions were, therefore, converted into the nitrate, the solution treated with a saturated solution of potassium sulphate, and the mixture kept for three days, with frequent shaking; the precipitated double salt and the excess of potassium sulphate were then separated. The double salt obtained after the third such treatment contains an earth, RO = 119·83, which, as a nitrate, shows only very feebly the absorption lines of samarium. The gadolinium earth in solution has the equivalent RO = 120·18 or R_2O_3 = 360·54, so that its atomic weight is R = 104·22 or R‴ 156·33, as the average of three determinations; a spectroscopic examination of a concentrated solution of its nitrate showed only faint indications of the presence of samarium, and the absence of all other absorption lines.

The strongly ignited gadolinium earth is of a faint yellow colour, and dissolves freely in acids, yielding colourless salts; when gently heated in a stream of hydrogen, it becomes colourless, but without change in weight; on strongly igniting the oxide in an atmosphere of hydrogen, it loses weight (0·11 per cent.) and seems to undergo partial reduction, assuming a faint, greyish hue; on heating in the air, it regains its original weight and its original colour; when the greyish oxide is treated with very dilute hydrochloric acid in the cold, there remains a small quantity of a substance of a rather darker shade. The spectrum of the gadolinium earth shows an orange-red line of great brightness and sharpness, the centre of which has the wave-

length $\lambda = \mu\mu$ 6094; there are also to be seen indications of bands, but they are extremely feeble. The author could not obtain the spark spectrum of gadolinium chloride which has been described by Lecoq de Boisbaudran (*Compt. rend.*, **111**, 472). F. S. K.

Action of Superheated Water and Solutions of Alkalis and of Salts on Glass. By F. Foerster (*Ber.*, **25**, 2494—2518; compare Abstr., 1889, 828; Weber and Sauer, this vol., p. 1052).—When a sealed glass tube, partially filled with water, is heated in aniline vapour for six hours, the portion exposed to the action of the vapour alone, becomes coated with a white, opaque layer, consisting chiefly of alkali silicates, together with calcium silicate and a small quantity of aluminium silicate. The superheated water acts in the same manner as at a lower temperature. Experiments made with different kinds of boiler-gauge glass showed great variation in their stability to superheated water; the glass specially prepared at Jena for this purpose giving the best results.

Solutions of caustic alkalis have a much stronger action on glass than water, inasmuch as they dissolve the glass as a whole, and not merely certain portions of it. Of equivalent solutions of the alkalis, soda has the strongest action, then potash, ammonia, and baryta in the order given; in all cases the action is greater the higher the temperature. At the ordinary temperature, dilute solutions act on the glass more readily than concentrated, but at higher temperatures the action increases with increase of strength, first very rapidly and then more slowly; pure solutions of the alkalis act much less readily than those containing small quantities of silicic acid as impurity. The extent of the action in all these cases is, as would be expected, dependent on the nature of the glass.

Solutions of the alkali carbonates attack glass more rapidly than water, but the nature of their action corresponds more with that of salts than with that of the alkalis. The action of other salts appears to depend partly on the concentration and nature of the salt, and partly on the reactions which take place between it and the substances extracted from the glass. H. G. C.

Analysis of Slag of Metallic Appearance from the Manufacture of Phosphorus in Electrical Furnaces. By J. C. Chorley (*Chem. News*, **65**, 301—302).—In the manufacture of phosphorus from a mixture of natural aluminium phosphate, calcium phosphate, carbon, and sand in an electrical furnace, two kinds of slag are obtained: the predominating one consists chiefly of calcium and aluminium silicates; the other, apparently a mixture of iron silicides and phosphide in varying proportions, yielded in the analysis of three samples from about 68 to 74 per cent. of iron, 9 to 14 per cent. of phosphorus, and 10 to 19 per cent. of silicon. It is found distributed through the mass in very hard, brittle buttons, of a steel-grey colour, and appears quite homogeneous, but not crystalline. Its sp. gr. is 5·965, its sp. heat 0·146, and it conducts electricity. It is not attacked by hydrofluoric, hydrochloric, nitric, nitrohydrochloric, or dilute sulphuric acid, and is only partially decomposed when boiled

with concentrated sulphuric acid; it is, moreover, only superficially affected by hydrogen sulphide, and but slightly acted on by bromine or iodine. To decompose it for analysis, it is either heated, in a finely-powdered condition, in a current of chlorine, when the iron, phosphorus, and silicon volatilise as chlorides, silica alone remaining behind; or it is heated with excess of a neutral solution of copper sulphate in a closed tube, at 170°, for 4 or 5 hours; no gas is evolved, plenty of copper mixed with copper phosphide is precipitated, and some iron, phosphorus, and silicon are dissolved. The contents of the tube are treated with nitric acid and the undissolved residue is fused with fusion mixture before examination in the ordinary way; whilst the nitric acid solution is evaporated with hydrochloric acid, the silica estimated, the copper removed as sulphide, and the solution containing some of the iron, &c., mixed with the main solution at the proper stage. D. A. L.

The Action of Nitric Acid on Metals. By C. Montemartini (*Gazzetta*, **22**, 384—397, 397—407, 426—436; compare this vol., p. 1278).—Much contradiction exists as to the changes which occur when nitric acid acts on tin. The author finds that the acid, up to a concentration of 12 per cent., always attacks tin with formation of stannous salt, which partially decomposes, forming a turbid solution; gas is always evolved, although slowly. Nitric acid from 12 to 45 per cent. completely dissolves the metal to a yellow solution, with abundant evolution of gas; the solution, when left, slowly becomes turbid, but the precipitation may be retarded by adding hydrochloric acid. The tin is present in these solutions as stannous nitrate, and the turbidity is due partly to the oxidation of this salt and partly to its conversion into insoluble stannous compounds, which, in turn, yield stannic hydrate. Nitric acid of more than 45 per cent. concentration does not dissolve tin, but converts it into a white substance. If 70 per cent. acid is used, this white oxidation product is soluble in water, but the solution, after a few seconds, becomes turbid, and stannic hydrate is deposited; the addition of hydrochloric acid to the clear solution greatly retards the precipitation. The soluble, white substance is found by analysis to be stannic nitrate, $Sn(NO_3)_4$; it is stable in presence of concentrated nitric acid at 90°, but is immediately decomposed at 100°.

The solution of 1 gram of tin in excess of 27·5 per cent. acid yields 0·0180 gram of ammonia, 0·1060 gram of nitrous oxide, and 0·0051 gram of nitrogen. The maximum quantity of ammonia is obtained when 1 per cent. nitric acid is used, but the rate of diminution in the amount of this gas produced, as stronger acid is used, is small; even 70 per cent. acid causes the formation of much ammonia. The hypothesis that the nitric acid is reduced by nascent hydrogen is insufficient for the explanation of the phenomena observed during the action of nitric acid on tin.

Contrary to the statements of Personne (*Bull. Soc. Chim.*, 1864, i, 163) and Maumené (*Ann. Chim. Phys.* [4], **3**, 343), the action on antimony of nitric acid, varying in concentration from 2 to 70·27 per cent., does not yield appreciable quantities of ammonia; 2 per cent.

acid has very little action on the metal. Antimony is not dissolved by nitric acid; a white powder always remains; when 70 per cent. acid is used, this residue seems to have the composition $(SbO)NO_3$. Nitric peroxide is practically the sole gas produced when this metal is used.

Molybdenum is attacked by 3 to 70 per cent. acid without the formation of ammonia. Concentrated acid (70 per cent.) attacks the metal but slowly; a much more vigorous action occurs with weaker acid (50 per cent.), and a reddish solution and residue are obtained. The solution reduces permanganate, so that the metal is not immediately converted into molybdic anhydride by 50 per cent. acid, but a nitrate would seem to be first formed; 70 per cent. acid at once gives molybdic anhydride. The quantity of nitric oxide produced in the reaction between nitric acid and molybdenum decreases as the concentration of the acid increases; nitric peroxide is the main gaseous product with 50 per cent. acid. Neither nitrogen nor nitrous oxide is formed.

No appreciable amount of ammonia is produced in the reaction between copper and 3 or 27·5 per cent. nitric acid. Dilute acid (below 30 per cent.) yields only nitric oxide and nitrous acid; with stronger acid, the gas evolved is principally nitrogen tetroxide, but small quantities of the trioxide are also formed. With acid of less than 30 per cent. concentration, the reaction is represented by the equation $Cu + 3HNO_3 = Cu(NO_3)_2 + HNO_2 + H_2O$. Nitric oxide is then formed in accordance with the equation $3HNO_2 = 2NO + HNO_3 + H_2O$. Nitric peroxide only is obtained with 70 per cent. acid.

Below 15°, nitric acid of all concentrations attacks pure lead very slowly; rather dilute acid acts the most rapidly. Small quantities of ammonia are formed, the amount being greatest with weak acid.

The action of nitric acid (27·5 and 70 per cent.) on bismuth yields neither ammonia, nitrogen, nor nitrous oxide. More nitric oxide is obtained with dilute than with concentrated acid, and owes its origin to secondary action. 27·5 per cent. acid gives no nitric peroxide, but this gas is the main product if 70 per cent. acid be employed.

The reaction between nitric acid and aluminium proceeds very slowly; with 27·5 per cent. acid no ammonia was obtained.

Mercury yields no ammonia with 27 and 50 per cent. acid; the quantity of nitric oxide produced, diminishes as the concentration increases. 27·5 per cent. acid gives no nitric peroxide, but stronger acid yields large quantities just as in the cases of copper and bismuth. Mercurous nitrate is obtained in solution on operating with 25 per cent. acid; more concentrated acid (50—70 per cent.) gives the mercuric salt.

Nitric acid (27·5 per cent.) gives no ammonia with silver, but only nitric oxide and nitrous acid.

The amount of ammonia produced in the reaction between magnesium and nitric acid increases with the concentration of the latter until 40 per cent. acid is reached, the quantity then decreases. Much hydrogen is formed; the mixture of this gas and nitric oxide liberated by 13 per cent. acid may be exploded by an electric spark.

Ammonia is produced by the action of nitric acid on manganese; so much hydrogen is formed that the evolved gas will not explode until oxygen has been added. Nitrogen and nitrous oxide are also liberated.

In all the previous experiments, excess of nitric acid was employed and the temperature was kept constant (15—20°).

The metals may be classed in three groups, according to their behaviour towards nitric acid. To the first group belong those metals which, with nitric acid, yield only nitrous acid, nitric oxide, nitrogen trioxide, and nitric peroxide. Metals of the second group give, besides these products, hyponitrous acid, nitrous oxide, nitrogen, and ammonia. In addition to these, metals of the third group liberate hydrogen. It is to be noted that metals belonging to the first group either do not decompose water at all or only at very high temperatures. Metals of the second group decompose water at much lower temperatures, and those of the third group act on water either at ordinary or at comparatively low temperatures. There is hence a relation between the products of the action of nitric acid on metals and the behaviour of the metals towards water; this relation supports the author's view that water sometimes takes part in the reaction.

The author considers that the reaction between nitric acid and metals which do not decompose water may be represented by the equation

$$M + 3HNO_3 = M(NO_3)_2 + HNO_2 + H_2O,$$
$$\text{or } M + 4HNO_3 = M(NO_3)_2 + 2NO_2 + 2H_2O,$$

according as the acid used is dilute or concentrated. To explain the formation of nitrogen trioxide, the following equation is employed, $2M + 6HNO_3 = 2M(NO_3)_2 + N_2O_3 + 3H_2O$. When water plays a part in the reaction, a more complex series of equations is necessary.

W. J. P.

Mineralogical Chemistry.

New Silver Ore. By H. N. Warren (*Chem. News*, **66**, **42**).—Hard, horny particles of ore containing traces of gold and silver iodide, bromide, and chloride, either, as in some samples, alone, as in others associated together, have been found disseminated through kaolinised deposits in the Broken Hill district of Australia.

D. A. L.

Jacobsite and Braunite from Sweden. By L. J. Igelström (*Zeit. Kryst. Min.*, **20**, 375; from *Geol. Fören. Förh.*, **12**, 137—139).—At the Glakärn mine, in the parish of Linde, the predominating ores are jacobsite and braunite. An analysis of the former mineral gave the following results:—

Fe_2O_3.	MnO.	MgO.	Insoluble in hydrochloric acid.
57·55	36·74	0·72	6·02

This is a new locality for these two minerals. B. H. B.

Braunite and Friedelite from Sweden. By G. Flink (*Zeit. Kryst. Min.*, **20**, 368—372; from *Bihang Sv. Vet. Akad. Handl.*, **16**, 1—23).—1. *Braunite from Långbanshyttan.*—The author has made a crystallographical examination of this mineral, and has observed five new planes: 4P∞, P2, $\frac{3}{4}$P∞, $\frac{4}{5}$P$\frac{3}{2}$, and $\frac{5}{4}$P$\frac{5}{2}$. The planes ∞P and P∞, observed by the author, have previously been noticed on braunite from other localities, but are new for braunite from Långbanshyttan. An analysis of this mineral gave the following results:—

SiO_2.	MnO.	O.	FeO.	CaO.	MgO.	Total.
9·89	78·91	7·35	3·81	0·34	0·15	100·45

This composition corresponds with a mixture of $MnMnO_3$ with $(Mn,Fe,Ca,Mg)SiO_3$. The sp. gr. of the mineral is 4·72.

2. *Friedelite from Harstigen.*—Although pyrosmalite hitherto has been found only in Sweden, the corresponding manganese mineral, friedelite, has been found only at Adervielle, in the Pyrenees. In 1889 it was, however, discovered at the Harstig mine in small crystals with pyroxene, magnetite, chlorite, and galena. The crystals are transparent and of a pink colour, with a hardness of 4 to 5, and a sp. gr. of 3·058. Analysis gave the following results:—

SiO_2.	Cl.	MnO.	FeO.	CaO.	MgO.	Mn.	H_2O.	Total.
34·66	4·04	42·48	4·08	0·53	2·27	3·13	8·47	99·66

B. H. B.

Limonite in Texas. By R. A. F. Penrose (*Jahrb. f. Min.*, 1892, ii, Ref. 18; from *First Annual Report Geol. Survey of Texas*, 66—83).—Limonite beds, 1 foot to 3 feet in thickness, overlying glauconite sands, occur in Cherokee, Anderson, and other counties in the east of Texas. The ore is sometimes laminated, sometimes massive or forming botryoïdal masses. The origin of the laminated and massive varieties is traced to the weathering of iron pyrites, and that of the botryoïdal masses to the oxidation of iron carbonate. The author gives numerous analyses, three of which are as follows:—

	Fe_2O_3.	Al_2O_3.	MnO.	MgO.	CaO.	SO_3.	SiO_2.
I.	59·20	11·20	—	—	trace	—	16·20
II.	65·79	8·31	—	trace	2·30	0·36	18·77
III.	74·11	16·50	0·13	1·77	1·04	0·93	1·49

	K_2O.	Na_2O.	P_2O_5.	Loss.	Total.
I.	—	—	trace	13·45	100·05
II.	—	—	trace	5·05	100·48
III.	0·36	0·49	0·12	—	97·94*

* In the original this total is given as 98·08.

I. Massive ore, Henderson Co. II. Laminated ore, north-east corner of Upshur Co. III. Limonite geode from Berry Hill, Marion Co. B. H. B.

Titaniferous Iron Ore and Manganese Spar from the Fichtelgebirge. By F. v. SANDBERGER (*Jahrb. f. Min.*, 1892, ii, Mem. 37—43).—1. *Titaniferous Iron Ore.*—The Eger contains at several places black metallic grains, undoubtedly produced from disintegrated lithionite-granite. A large quantity of this mineral from the sand at Röslau showed that the form of the grains is hexagonal with a tabular development. The colour is dark steel-grey, the streak black, and the sp. gr. 4·659. The ore is non-magnetic. Analysis gave the following results :—

TiO_2.	Fe_2O_3.	FeO.	MgO.	Total.
48·12	24·95	27·96	0·29	101·32

2. *Manganese-spar from Arzberg.*—At Arzberg a manganese carbonate has recently been discovered. It forms a thick layer on chalybite. Its sp. gr. is 3·59. Analysis yielded :—

$MnCO_3$.	$FeCO_3$.	$CaCO_3$.	SiO_2.	Total.
84·41	14·22	0·54	0·40	99·57

This is the richest in iron of all the manganese spars hitherto analysed.

The remainder of the author's paper is devoted to descriptions of (3) margarodite, a secondary mica from the lithionite-granite of Epprechtstein, (4) pseudomorphs of chlorite after orthoclase from the Strehlenberg, (5) pseudomorphs of quartz after orthoclase from the same locality, and (6) lithium-mica from Tröstau, near Wunsiedel, a mica very similar in composition to that from the pegmatite of Penig, in Saxony. B. H. B.

Triplite and Kaolin from the United States. By L. G. EAKINS (*Zeit. Kryst. Min.*, **20**, 494; from *Bull. U.S. Geol. Surv.*, **60**, 135—136).—The specimen of triplite analysed (I) was obtained from a tin mine at Rapid City, South Dakota. It is of a brown colour, and translucent in small fragments. The kaolin analysed (II) forms a fine white mass, filling the cavity in the Rodwell Basin, Gunnison Co., Colorado. In it crystals of pyrites and galena are found. The analyses gave :—

	SiO_2.	Al_2O_3.	Fe_2O_3.	FeO.	MnO.	CaO.	K_2O.	Na_2O.	Li_2O.
I.	0·43	8·74	2·36	1·97	29·13	6·72	trace	5·25	0·13
II.	47·28	36·19	trace	—	—	0·42	5·74	0·51	—

	P_2O_5.	H_2O.	F.	Cl.	CO_2.	Total.
I.	39·68	3·67	2·35	0·25	0·26	100·94
II.	0·57	8·72	—	—	—	99·43

B. H. B.

Manganese-spar and Celestine from Scharfenberg. By H. ZINKEISEN (*Jahrb. f. Min.*, 1892, ii, Ref. 68—69).—In a geological

description of the Güte Gottes mine at Scharfenberg, on the left bank of the Elbe above Meissen, the author gives analyses of the manganese-spar (I) characteristic of the deposit, and of celestine (II) which is of frequent occurrence in well developed crystals. The analytical results were as follows :—

	MnO.	SrO.	FeO.	CaO.	MgO.	BaO.	CO_2.	SO_3.	Total.
I.	52·40	trace	5·13	3·06	0·77	trace	38·53	—	99·89
II.	—	55·32	—	0·80	—	0·18	—	44·10	100·40

B. H. B.

Minerals from the Pacific Coast. By W. H. Melville and W. Lindgren (*Zeit. Kryst. Min.*, **20**, 495—498; from *Bull. U.S. Geol. Surv.*, **61**, 11—31).—1. *Sulphates.*—The author gives analyses of three sulphates found in strings in a black opal at the Redington Quicksilver mine, Knoxville, California. The first occurs in small, black, regular crystals, and is a double sulphate of potassium and iron. The second consists of fibrous masses of redingtonite (sp. gr. 1·761), and the last, termed *knoxvillite* by the authors, forms thin crusts on the redingtonite. Analyses are also given of copiapite from the same locality, and of a yellow sulphate from the Sulphur Bank, Lake Co., California, which was found optically to be identical with copiapite. As all these salts were moist, the proportion of water cannot be utilised in the discussion of their formulæ; the molecular ratios of the anhydrous salts were :—

Redingtonite	$6RO,4R_2O_3,19SO_3$,
Knoxvillite	$6RO,6R_2O_3,15SO_3$,
Copiapite	$3RO,6R_2O_3,17SO_3$,
Yellow sulphate (Sulphur Bank)	$3RO,9R_2O_3,25SO_3$.

2. *Stromeyerite.*—An analysis is given of stromeyerite from the Silver King mine, Calico, San Bernardino Co., California. The ore is of a dark, steel-grey colour, and is accompanied by barytes, malachite, and a brown manganic oxide. Its sp. gr. is 6·28. The analytical results were :—

Ag.	Cu.	S.	Fe.	Residue.	Total.
53·96	28·57	15·51	0·26	1·55	99·85

The residue consists of barytes with a little quartz. B. H. B.

Thaumasite, Wollastonite, Chabasite, and Vesuvian. By O. Widman (*Zeit. Kryst. Min.*, **20**, 373—375; from *Geol. Fören. Förh.*, **12**, 20—29).—1. *Thaumasite.*—This mineral has been found between apophyllite in veins in gneiss at Kjölland, 13 miles from the best known locality for this mineral, the Bjelkes mine, at Åreskutan. Analyses of the mineral from the two localities gave results corresponding with the formula $CaSiO_3,CaCO_3,CaSO_4,15H_2O$.

2. *Wollastonite from Perheniemi, Finland.*—Two varieties were analysed, one with a vitreous lustre and laminated texture, the other with a silky lustre and fibrous texture. The results were as follows :—

SiO_2.	CaO.	FeO.	H_2O.	Total.
51·49	47·65	0·26	0·60	100·00
51·23	47·37	1·08	0·32	100·00

3. *Chabasite from the Faroe Islands.*—The mean of three analyses of this mineral was as follows:—

SiO_2.	Al_2O_3.	CaO.	Na_2O.	K_2O.	H_2O.	Total.	Sp. gr.
45·85	19·83	8·86	2·35	0·63	22·26	99·78	2·09

The formula is therefore $Ca(Na_2K_2)SiO_3,Al_2(SiO_3)_3,6H_2O$.

4. *Vesuvian.*—The author gives the following results of analyses of vesuvian (I) from Arendal and (II) from Hamrefjeld, Norway:—

	SiO_2.	TiO_2.	Al_2O_3.	Fe_2O_3.	MnO.	CaO.	MgO.	B_2O_3.
I.	35·45	—	12·18	7·29	1·88	34·01	4·56	1·96
II.	35·19	1·63	11·53	5·74	2·00	38·34	2·72	—

	F.	H_2O.	Total.	
I.	—	3·14	100·47	
II.	1·97	0·89	100·01	B. H. B.

Pholidolite, a New Mineral. By G. Nordenskiöld (*Zeit. Kryst. Min.*, **20**, 382—386; from *Geol. Fören. Förh.*, **12**, 348—358).—In cavities in the Taberg mine in Wermland, Sweden, fine crystals of diopside, garnet, and other minerals occur, together with an earthy mass which fills the cavities. This mass consists of yellow scales with crystals of diopside, garnet, epidote, apatite, titanite, magnetite, chlorite, and galena. It is, in fact, a kind of crystal-breccia. The yellow scales appear to belong to a new mineral, for which the author suggests the name of *pholidolite*. The sp. gr. of the mineral is 2·408. The analysis of the mineral gave results corresponding with the formula $13SiO_2,Al_2O_3,12(FeMg)O,K_2O,5H_2O$, and the author considers that the mineral is composed of the following compounds:—

1 magnesium silicate	$Mg_6Si_3O_{12},H_4Si_5O_{12}$.
$\frac{1}{3}$ potassium mica silicate	$K_2Al_2Si_2O_8$.
1 silicate	$H_3Mg_3(MgOH)_3Si_3O_{12}$.

B. H. B.

The Pyroxene Family. By E. A. Wülfing (*Jahrb. f. Min.*, 1892, ii, Ref. 23).—The author has endeavoured to determine the relations between the chemical composition and the optical properties of augites, especially of those free from alumina. The pyroxenes examined were: 1. Diopside from Nordmarken, type V. 2. From the Alathal. 3. From Nordmarken, type IV. 4. From Nordmarken, type I. 5. Hedenbergite from Tunaberg. 6. Ægirine from Langesundfjord. With regard to the chemical composition of the diopsides, the author finds that they should be regarded neither as mixtures of $CaMgSi_2O_6$ with $CaFeSi_2O_6$, nor as mixtures of $CaOSiO_2$, $MgOSiO_2$, and $FeOSiO_2$, but as a mixture of three primary constituents, $CaOMgO2SiO_2$, $CaOFeO2SiO_2$, and $MgOFeO2SiO_2$. The percentage

amounts of the primary constituents are shown in the following table:—

	I.	II.	III.
$CaO,MgO,2SiO_2$	90·4	35·0	8·0
$CaO,FeO,2SiO_2$	8·6	60·4	84·8
$MgO,FeO,2SiO_2$	1·0	0·6	5·2
MgO,Al_2O_3,SiO_2.....	—	—	2·0
H_2O,SiO_2	—	1·4	—
Fe_2O_3,SiO_2	—	2·6	—
	100·0	100·0	100·0

I, mean of the composition of the first three diopsides; II, diopside of Nordmarken, type I; and III, hedenbergite. B. H. B.

Analyses of Pyroxene. By T. M. Chatard (*Zeit. Kryst. Min.*, **20**, 501; from *Amer. Geologist*, **6**, 35).—In a description of the non-felspathic intrusive rocks of Maryland, the author notes that the fine pyroxenite of Hebbville, west of Baltimore, consists of typical, reddish-brown bronzite (Analysis I) and of emerald-green diopside (Analysis II):—

	SiO_2.	TiO_2.	Al_2O_3.	Cr_2O_3.	Fe_2O_3.	FeO.	MnO.	CaO.
I.	54·53	—	1·93	0·30	1·70	8·92	0·28	2·25
II.	51·80	0·13	2·21	0·51	1·29	3·50	trace	20·99

	MgO.	H_2O.	Total.	Sp. gr.
I.	29·51	1·14	100·56	3·300
II.	17·76	0·65	98·84	3·308

B. H. B.

Garnierite from Norway. By C. A. Münster (*Zeit. Kryst. Min.*, **20**, 402; from *Archiv. matematik naturvidenskab.*, **14**, 240).—At Foldalen, in Norway, this mineral occurs in a thin layer. On analysis, it gave the following results:—

SiO_2.	MgO.	NiO.	FeO.	H_2O.	Total.
44·55	21·03	5·45	9·87	18·71	99·61

The surrounding rock contains 0·33 per cent. of nickel.

B. H. B.

Allanite from Gyttorp, Sweden. By G. Nordenström (*Zeit. Kryst. Min.*, **20**, 386—387; from *Geol. Fören. Förh.*, **12**, 540).—In a recently-opened iron mine at Gyttorp, allanite has been discovered in great abundance. It occurs in granulite as lenticular masses surrounded by dark mica. Analysis of the mineral gave the following results:—

SiO_2.	$Fe_2O_3 + Al_2O_3$.	FeO.	Ce_2O_3.	CaO.	MgO.	H_2O.	Alkalis and loss.
29·60	21·42	9·51	24·72	7·75	4·25	0·67	2·18

B. H. B.

Gadolinite. By C. W. Blomstrand (*Zeit. Kryst. Min.*, **20**, 366).—Analyses of gadolinite from Ytterby (I) and from Hitterö (II) gave results in good accord with the formula $Be_2Fe(YO)_2(SiO_4)_2$, which the author regards as the rational formula for gadolinite. The analytical results were as follows:—

	SiO_2.	ThO_2.	Ce_2O_3.	$(La,Di)_2O_3$.	$(Y,E)_2O_3$.	Al_2O_3.	Fe_2O_3.	FeO.
I.	23·84	0·31	0·92	3·33	47·06	0·12	0·21	12·97
II.	23·72	0·35	6·67		45·62	—	—	12·19

	MnO.	BeO.	MgO.	CaO.	PbO.	Na_2O.	Total.
I.	0·12	10·55	0·07	0·35	0·05	0·18	100·08
II.	0·16	10·10	0·26	0·37	0·05	0·19	99·68

B. H. B.

Gadolinite. By W. Petersson (*Zeit. Kryst. Min.*, **20**, 376—383; from *Geol. Fören. Förh.*, **12**, 275—347).—The author has made an exhaustive study of the composition of gadolinite, and his paper contains the results of analyses of this mineral from Hitterö, from Ytterby, from Broddbo, from Finbo, from Gamla Kårarfvet, from Nya Kårarfvet, from Torsåker, from Karlberg, from Grimstad, and from other Scandinavian localities. The investigation has led to the conclusion that gadolinite is characterised by a constant fairly high proportion of beryllium, regardless of the locality from which the mineral is derived and of its physical condition. The view hitherto held that gadolinite existed free from beryllium or poor in that metal has thus not been confirmed. The author therefore adopts for gadolinite the formula $Be_2FeY_2Si_2O_{10}$ or $Be_2Fe(YO)_2(SiO_4)_2$ (compare Abstr., 1891, 1168). B. H. B.

The Formula of Tourmaline. By A. Kenngott (*Jahrb. f. Min.*, 1892, ii, Mem. 44—57).—This paper was suggested by the publication of three analyses by R. Scharizer (Abstr., 1889, 764) of the tourmaline from Schüttenhöfen, in Bohemia. By calculations based on these three analyses and on 20 analyses of American tourmalines published by R. B. Riggs (Abstr., 1888, 659), the author concludes that the tourmalines form a series of silicates in which, if the oxides Al_2O_3, B_2O_3, Fe_2O_3, and Mn_2O_3 are grouped together as R_2O_3, the MgO, CaO, FeO, and MnO as RO, and H_2O, Na_2O, K_2O, and Li_2O as R_2O, two isomorphous silicates, A and B, are contained in varying quantities. For the silicate A the calculated formula is $3R_2O,SiO_2 + 5(R_2O_3,SiO_2)$, and for the silicate B the formula is $2(3RO,SiO_2) + R_2O_3,SiO_2$. The author's calculations were extended to the analyses of P. Jannasch and G. Calb (Abstr., 1889, 472; 1891, 24) and to those of Rammelsberg (Abstr., 1891, 24), so that altogether 45 analyses were considered. B. H. B.

Composition of Melilite. By J. H. L. Vogt (*Jahrb. f. Min.*, 1892, ii, Mem. 73—75).—The author points out that the composition of the artificial melilite formed during the burning of Portland cement in an annular kiln, and analysed by G. Bodländer (this vol.,

p. 416), does not accord with the theoretical composition of a mixture of gehlenite and akermanite, the two terminal members of which the melilite series, according to the author, is composed. Nor does the analysis agree with older analyses of natural melilite, Bödländer's analysis showing too much RO (CaO,MgO,K_2O,Na_2O). By a microscopical examination of some of Bödländer's original material, the author finds that, owing probably to the presence of cement-dust, the mineral was not chemically pure. For this reason, the analysis is not available either to confirm or to confute the author's theory of the composition of the melilite series. B. H. B.

Petalite, Spessartine, and Willemite. By F. W. Clarke (*Zeit. Kryst. Min.*, **20**, 493; from *Bull. U.S. Geol. Surv.*, **60**, 129).—Analyses of petalite from Peru, Maine, (I) forming white masses with pearly lustre, and of spessartine (II) from Amelia Co., Virginia, gave the following results:—

	SiO_2.	Al_2O_3.	Fe_2O_3.	FeO.	MnO.	CaO.	Li_2O.	Na_2O.	Loss on ignition.
I.	77·29	19·95	trace	—	trace	—	2·62	2·39	1·03
II.	35·35	20·41	2·75	1·75	38·70	0·94	—	—	0·27

An analysis of willemite from the Trotto mine, Franklin, New Jersey, gave—

SiO_2.	ZnO.	Loss on ignition.
27·41	68·86	0·25

B. H. B.

Minerals of the Harstigen Mine, Sweden. By A. Hamberg (*Zeit. Kryst. Min.*, **20**, 387—402; from *Geol. Fören. Förh.*, **12**, 567—632).—1. *Manganophyll.*—The highly manganiferous mica from the Harstigen mine, near Pajsberg, in Wermland, was first observed by Igelström, and named manganophyll. Analysis of two varieties—I, reddish-brown, and II, dark-brown—gave the following results:—

	SiO_2.	Al_2O_3.	Fe_2O_3.	Mn_2O_3.	MnO.	FeO.	CaO.	MgO.	K_2O.
I.	40·64	9·43	3·66	—	9·63	0·05	—	22·31	10·50
II.	36·42	12·64	3·80	0·70	17·13	—	0·20	14·73	8·78

	Na_2O.	Li_2O.	H_2O.	F.	Total.
I.	0·35	0·29	4·30	0·30	101·46
II.	0·38	0·40	4·60	0·33	100·11

Although the composition of manganophyll does not accord with the formulæ for biotite proposed by Tschermak, Knop, Clarke, and others, there can be no doubt that this mineral should be regarded as a manganiferous biotite.

2. *Manganiferous Chlorite.*—This mineral occurs with manganophyll in veins filled with calcite. On analysis, it gave results corresponding with the formula

$$3(2H_2O,3MgO,2SiO_2) + 2(2H_2O,2MgO,Al_2O_3,SiO_2),$$

proposed by Tschermak for pennine, some of the magnesia being replaced by manganese.

3. *Ganophyllite.*—This new mineral, named after the high lustre (*γάνος*) of the laminæ (*φύλλον*) occurs in fairly large, monosymmetric crystals. Analysis gave results in accord with the formula

$$8SiO_2,Al_2O_3,7MnO,6H_2O.$$

4. *Pyrophanite.*—With ganophyllite, a second new mineral has been discovered. It is of a red colour, and proves to be a compound isomorphous with titaniferous iron ore, and having the composition $MnTiO_3$, analysis having given the following results:—

SiO_2.	TiO_2.	MnO.	Fe_2O_3.	Sb_2O_3.	Total.
1·58	50·49	46·92	1·16	0·48	100·63

This is the first titaniferous mineral found in Wermland.

B. H. B.

Helvine from Hungary. By A. Kalecsinszky (*Zeit. Kryst. Min.*, **20**, 365).—Helvine from Kapnikbánya, sp. gr. 3·203, gave on analysis the following results:—

SiO_2.	MnO.	BeO.	Mn.	FeO.	S.	Total.
32·82	36·40	13·45	9·02	0·66	5·25	97·60

B. H. B.

Products of the Weathering of Diabase. By R. Brauns (*Jahrb. f. Min.*, 1892, ii, Mem. 1—24).—Opposite Friedensdorf, near Marburg, on the left side of the Lahn, a diabase has been opened up by an extensive quarry. This diabase is of special interest on account of the numerous minerals of secondary formation occurring in fissures in it. It is for the most part a normal felspar-diabase, in which the augite can be detected with the naked eye, whilst the felspar is less distinct. The mass of rock has a columnar structure, and is traversed by numerous fissures, whose walls are covered with minerals of secondary formation, in some cases with analcime alone, with prehnite alone, with albite alone, or more frequently with prehnite, analcime, and calcite, or more rarely with these minerals together with albite. Natrolite occurs, but only to a subordinate extent. These minerals are described in detail by the author, and analyses of each are given. The order in which the minerals have been formed is probably as follows:—Analcime, albite, prehnite, prehnite and calcite, analcime of second formation, calcite. In some cases, however, albite is also older than analcime. In conclusion, the author discusses the manner in which these compounds have been produced from the weathering of lime-soda-felspar. The formulæ of these compounds are as follows:—

Lime-soda felspar:	$Na_2Al_2Si_6O_{16}$	Albite.
$Na_2Al_2Si_6O_{16}$	$Na_2Al_2Si_4O_{12},2H_2O$ ..	Analcime.
	$Na_2Al_2Si_3O_{10},2H_2O$ ..	Natrolite.
	$H_2Ca_2Al_2Si_3O_{12}$.....	Prehnite.
$Ca_2Al_4Si_4O_{16}$	$HCa_2Al_3Si_3O_{13}$	Epidote.
	$CaCO_3$	Calcite.

B. H. B.

Analcime as a Rock-forming Mineral. By W. Lindgren (*Zeit. Kryst. Min.*, **20**, 498—499; from *Proc. Calif. Acad. Sci.*, **3**, 39).—In the Cretaceous sandstones of the Highwoods, Rocky Mountains, in Montana, veins occur of a basaltic rock composed of augite, olivine, magnetite, and crystals of analcime. An analysis of the crystals (sp. gr. 2·20) gave—

SiO_2.	Al_2O_3.	CaO.	MgO.	Na_2O.	K_2O.	H_2O.	Total.
54·90	23·30	1·90	0·70	10·40	1·60	7·50	100·30

B. H. B.

Proportion of Fluorine in Fossil Bones of Various Ages. By A. Carnot (*Compt. rend.*, **115**, 243—246).—The proportion of fluorine in fossil bones is very much higher than in recent bones. In fossils from primary and secondary rocks, the ratio of fluorine to phosphoric acid is practically the same as in crystallised apatite. In tertiary and quaternary fossils, the proportion of fluorine is distinctly lower, and it gradually decreases with the age of the formation, always, however, remaining considerably higher than in recent bones. This fact may possibly be utilised to distinguish recent bones from quaternary bones with which they may have become mixed, but such a method would not be applicable to bones from different beds.

C. H. B.

New Meteorites. By E. E. Howell (*Jahrb. f. Min.*, 1892, ii, Ref. 33—36; from *Proc. Rochester Acad. of Science*, **1**, 86—100).—The author gives further particulars of the Welland, the Hamilton Co., the Puquois, the De Cewsville, and the El Chañaralino meteorites. He also describes two meteorites, the Doña Inez and Llano del Inca, found in Atacama, Chili, in 1888, during the survey of the frontier. They belong to the mesosiderite class. Pieces found near the Cerro de Doña Inez gave, on analysis, the following results:—

	SiO_2.	FeO.	Al_2O_3.	P_2O_5.	NiO.	CoO.	CaO.
I.	18·41	58·96	6·39	0·32	5·28	0·34	3·56
II.	52·87	20·96	7·52	—	0·72	trace	1·67
III.	2·94	75·84	5·89	0·46	7·33	0·48	4·42

	MgO.	S.	Cu.	Total.
I.	4·92	1·06	trace	99·24
II.	14·71	—	—	98·45
III.	0·53	1·54	trace	99·43

(1) Analysis of the mass; (2) analysis of the portion (29·77 per cent.) insoluble in hydrochloric acid; (3) analysis of the portion (70·23 per cent.) soluble in hydrochloric acid. The sp. gr. was 3·98. Under the microscope, the following constituents were detected: red monoclinic and colourless rhombic pyroxene, anorthite, olivine, magnetite, troilite, and nickeliferous iron. B. H. B.

Organic Chemistry.

Substitution in the Aliphatic Series. By V. Meyer and F. Müller (*J. pr. Chem.* [2], **46**, 161—188).—The continuation of the authors' experiments on the halogenation of alkyl halides (this vol., p. 577) shows that the normal course of the reaction must be considered to consist in the attachment of the newly-entering halogen atom to the carbon atom adjacent to the one which carries the already-contained halogen atom, and not to the same carbon atom, as has heretofore been accepted.

A repetition of Tawildarow's experiments (*Annalen*, **176**, 12) showed that ethylidene bromide is almost exclusively produced when the bromination of ethyl bromide is effected at 200°, whereas, as already stated (this vol., p. 577), ethylene bromide is the sole product when the reaction takes place at 100° in the presence of iron wire. The boiling point of ethylidene bromide is 107—108°, not 110—114°, as has been variously stated. The cause of the difference between these reactions was thought to be the spontaneous change of ethylene bromide into ethylidene bromide at 200°; but when ethylene bromide was heated in a sealed tube for 13 hours at this temperature, it was unchanged. Nor could ethylidene bromide be obtained from ethylene bromide by heating it with hydrogen bromide, hydrobromic acid, or bromine. Two other explanations of the reaction at 200° suggest themselves: (1) the ethylene bromide may, at the moment of its formation, decompose into vinyl bromide and hydrogen bromide, which re-combine again to form ethylidene bromide; (2) the change of orientation is similar to such as occurs when toluene, for example, is brominated under different conditions.

The bromination of ethylidene bromide, in the presence of iron, at 70—80°, yields 1 : 1 : 2-tribromethane. The chlorination of ethylidene chloride by antimony pentachloride in a reflux apparatus yields 1 : 1 : 2-trichlorethane (b. p. 111—112°). Ethylene chloride is not attacked by antimony pentachloride in a sealed tube at 100°. Both normal propyl chloride and isopropyl chloride yield propylene chloride (b. p. 96—98°) when treated with antimony pentachloride at normal pressure; in the case of the former, the mixture requires heating at 35—45°, but the reaction takes place at the ordinary temperature in the case of the latter.

The following reactions confirm the authors' views, if the identification of the products be correct. The brominations were effected by bromine in the presence of iron wire in a reflux apparatus at 50—60°, and the chlorinations by antimony pentachloride at the ordinary temperature.

Butyl bromide (1-bromobutane) yields a dibromide which boils at 157° and appears to be identical with pseudobutylene bromide (2 : 3-dibromobutane), in which case a change of orientation on the part of the bromine atom in butyl bromide must occur. The authors have been unable to effect such a change without the substitution by

bromine. *Secondary butyl bromide* (2-bromobutane, b. p. 90—93°) also yields pseudobutylene bromide. Isobutyl bromide (1-bromo-2-methylpropane) yields some isobutylene bromide (1 : 2-dibromo-2-methylpropane, b. p. 148—149°), but higher brominated products predominate. Tertiary butyl bromide (2-bromo-2-methylpropane) also yields isobutylene bromide; the reaction takes place at the ordinary temperature, and the production of higher brominated compounds is much smaller.

The chlorination of normal butyl chloride produces a dichloride which boils at 115—120°, and appears to be 2 : 3-*dichlorobutane*. Isobutyl chloride (1-chloro-2-methylpropane) and tertiary butyl chloride (2-chloro-2-methylpropane) both yield a dichloride which boils at 105—107°, and appears to be 1-chloro-2 : 2-chloromethylpropane; its boiling point agrees with that of d'Oetreppe's dichloride (*Jahresber.*, 1882, 441), and, less exactly, with that of the dichloride which Œconomides obtained by the action of phosphoric chloride on isobutaldehyde (Abstr., 1881, 709). A. G. B.

1 : 3-Dinitropropane. By F. Keppler and V. Meyer (*Ber.*, **25**, 2638).—The authors have obtained small quantities of trimethylenediamine platinochloride by adding glacial acetic acid (40 grams) to an aqueous solution (100 grams) of sodiodinitropropane (7 grams); sodium amalgam (500 grams of 2·5 per cent.) is now gradually added, and the temperature kept below 25° by cooling. The base is separated from the solution by E. Fischer's method (Abstr., 1884, 1289). W. J. P.

Action of Silver Nitrite on Methylene Iodide. By A. Russanow (*Ber.*, **25**, 2635—2637).—Iodonitromethane was obtained by V. Meyer (this vol., p. 575) by the action of silver nitrite on methylene iodide. It is prepared by adding silver nitrite (5 grams) to a solution of methylene iodide (3 grams) in ether (20 c.c.); a trace of iodine is added, the whole carefully heated to boiling for 45 minutes, and then allowed to remain for some hours at the ordinary temperature. The ethereal solution is filtered, and the residue repeatedly extracted with small quantities of ether. Absolute alcohol (1 vol.) is now added to the ethereal solution (1 vol.), and sodioiodonitromethane (0·5—0·8 gram) precipitated by the addition of sodium ethoxide. The precipitate is collected, washed first with a mixture of ether (1 vol.) and absolute alcohol (1 vol.), then with ether, and finally dried over sulphuric acid. The sodium derivative is a slightly hygroscopic, white powder, which explodes on heating and decomposes when kept. Its aqueous solution, acidified with sulphuric acid and extracted with ether, yields iodonitromethane as an oil of pungent odour, which very quickly decomposes, giving free iodine.

The sodium derivative may be diazotised, if great care be employed, by the use of diazo-salts; if excess of the latter be added, however, nitromethane derivatives, containing no iodine, are obtained. Slightly less than the theoretical quantity of diazo-salt is therefore used. Sodioiodonitromethane is dissolved in water (400 parts), and the ice-cold solution (50 parts) of the diazochloride added; the precipitate

is rapidly collected, washed with water, dissolved in a little ethyl acetate, diluted with much alcohol, and precipitated with water. The precipitate should give a carmine solution with concentrated sulphuric acid; if a violet or blue colour is obtained, nitromethane derivatives have been produced. The precipitate, after filtration, is generally pure.

Iodonitromethaneazobenzene, $NO_2 \cdot CHI \cdot N_2Ph$, is obtained by the above method in orange-yellow, microscopic needles. It melts at 110—112° with complete decomposition, and, with concentrated sulphuric acid, gives a carmine solution which soon turns grey.

Iodonitromethaneazotoluene closely resembles the preceding substance; it melts at 108—110°.

If the diazotisation be carelessly performed in a concentrated solution, cherry-red needles of azobenzenenitromethane, or of parazotoluenenitromethane, are respectively obtained. W. J. P.

Silver and Copper Compounds of Acetylene. By E. H. Keiser (*Amer. Chem. J.*, **14**, 285—290).—Acetylene was passed through ammoniacal solutions of cuprous or silver salts respectively. The precipitate was washed by decantation in tall cylinders, from which the air had been removed by a current of carbonic anhydride, using first dilute ammonia, then water, and finally alcohol and ether. It was then drained by the filter-pump and quickly transferred to a vacuum desiccator shielded from the light; the silver compound when dry, was snow-white. Specimens dried at the ordinary temperature contained from 89·31 to 89·44 per cent. of silver; a preparation dried at 100° in a vacuum contained 89·62 per cent. silver. The formula C_2Ag_2 requires 89·99 per cent.; Miasnikoff's formula (*Annalen*, **118**, 330), $C_2H_2Ag_2$, requies 89·25 per cent. of silver.

A weighed quantity exploded in a vacuum yielded but a very small quantity of gas, and that was almost entirely absorbed by potash; the residue consisted of carbon and finely divided silver. The formula C_2Ag_2 may therefore be considered as established.

The copper compound invariably contained free carbon; moreover the voluminous precipitate was usually contaminated with the substances in solution. The best result was obtained by the action of acetylene on cuprous hydroxide suspended in water. The analyses indicate that Cu_2C_2 is the formula of the compound. As in the case of silver, no hydrogen was obtained on explosion.

Action of Hydrogen Cyanide on Mercurous Salts. By D. Vitali (*L'Orosi*, **15**, 186—192).—Cheynet (*J. Pharm.*, 1892, 456), Fouquet (Abstr., 1890, 229), and others have described experiments to show that in the reaction between hydrogen cyanide and calomel, mercury, mercuric cyanide, and hydrogen chloride are formed. This is further confirmed by the following observations:—

On leaving pure calomel and very dilute hydrocyanic acid in contact for 24 hours, with occasional agitation, the calomel turns ash-

coloured, and the solution becomes strongly acid. This is due to the hydrogen cyanide, as, on adding a few drops to an alcoholic solution of Congo-red, it turns blue; an alcoholic solution of phenolphthaleïn reddened by soda is also decolorised.

The presence of hydrochloric acid is shown by the insolubility of the silver nitrate precipitate in nitric acid, and by the blackening of a silver dish in which a portion of the solution was placed together with a little potassium nitrite.

Mercuric chloride is absent from the solution, as no precipitate is obtained on adding excess of potash. The presence of mercuric cyanide in the solution is proved by expelling the free hydrogen cyanide at a gentle heat, passing hydrogen sulphide, and testing the liquid for hydrogen cyanide.

The absence of mercuric chloride was proved by titrating the solution with standard alkali in presence of phenolphthaleïn, before and after treatment with hydrogen sulphide, the acidity being actually somewhat lower in the latter case. S. B. A. A.

Fulminuric and Deoxyfulminuric Acids. By P. Seidel (*Ber.*, **25**, 2756—2759).—In a former paper (this vol., p. 690), the author described the formation of ethyl fulminurate and of an acid obtained from it by the action of boiling water or alcohol. This acid, *deoxyfulminuric acid*, $C_3H_3N_3O_2$, is best obtained by simply boiling the ethereal salt with water, as, if alcohol is used, further decomposition occurs with evolution of hydrogen cyanide, and the product is less pure. The acid is decomposed by hydrochloric acid at 110—120°. It could not be reconverted into fulminuric acid by the action of nitric acid or iodine solution. Most of its salts are coloured more or less. The *alkali*, *silver*, and *lead* salts are bright yellow, the *copper* salt greenish-black, the *nickel* salt pale-red, the *ferrous* salt violet, and the *ferric* salt pale-orange. The silver salt, $C_3H_2AgN_3O_2$, when precipitated from slightly acid solutions, can be recrystallised from boiling water, but if prepared from neutral or alkaline solutions, it always decomposes with separation of a pale-brown powder.

If, in the preparation of ethyl fulminurate, the heating is continued for some time, a *second ethyl fulminurate* is also formed. This is the principal product if the reaction is carried out at 100°. It crystallises with 1 mol. H_2O in long, colourless needles, melts at 155°, and decomposes above 175°. It is more soluble in alcohol than its isomeride. Both salts are decomposed by hydrochoric acid at 110—120°, and by alcoholic potash. When heated with a chloroform solution of ammonia, the ether of m. p. 133° yields ammonium deoxyfulminurate, whilst the new ether gives *fulminuramide*, $NH_2{\cdot}C_3H_2O_3N_3$. This crystallises in colourless needles insoluble in alcohol or ether, very sparingly soluble in boiling water, slightly more so in cold soda; it melts with decomposition above 250°. Unlike isofulminuramide, it does not give a double salt with ammoniacal copper solution.

Fulminuric acid thus forms two series of ethereal salts, of which the ethyl salt melting at 133° represents the oxy-salts, that melting at 155° the nitrogen salts. L. T. T.

Water of Crystallisation of Barium Thiocyanate. By J. Tcherniac (*Ber.*, **25**, 2627—2629).—Barium thiocyanate is generally stated to crystallise with 2 mols. H_2O; the author finds, however, that the pure crystallised salt has the composition $Ba(SCN)_2 + 3H_2O$, analogous to that of the crystallised thiocyanates of calcium and strontium. Commercial samples of the crystallised barium salt supposed to contain more thiocyanate than corresponds with 3 mols. H_2O are generally strongly contaminated with sodium salts.

Pure anhydrous barium thiocyanate dissolves readily in absolute alcohol, and the solution on concentration in a vacuum deposits transparent needles; these seem to have the composition

$$Ba(SCN)_2 + 2EtOH.$$

Similarly, anhydrous barium thiocyanate (1 part) dissolves in dry methyl alcohol (1·3 parts) with development of heat; on spontaneous evaporation of the solution, beautiful, lustrous, prismatic needles separate, having the composition $Ba(SCN)_2 + 2MeOH$.

W. J. P.

New Thiosulphates. By A. Purgotti (*Gazzetta*, **22**, 416—426).—Organic thiosulphates were prepared by Spring and Legras (Abstr., 1883, 47), who concluded that thiosulphates of saturated radicles are alone capable of existing. The author has, however, succeeded in preparing thiosulphates containing unsaturated groups.

Sodium allyl thiosulphate, $CH_2{:}CH{\cdot}CH_2{\cdot}S_2O_3Na + H_2O$, is obtained as follows:—Sodium thiosulphate and allyl chloride, in molecular proportion, are dissolved in water (2 vols.) and alcohol (1 vol.) respectively. The solutions are mixed, heated on the water-bath in a reflux apparatus for 4—5 hours, and the product evaporated at a temperature not above 50°. The residue is extracted with hot alcohol, and the solution on concentration yields the salt in beautiful laminæ, which are very soluble in water and hot alcohol. Its aqueous solution gives white precipitates with mercuric chloride and silver nitrate solutions, and is decomposed on boiling. When heated with hydrochloric acid, allyl mercaptan is obtained.

Sodium isopropyl thiosulphate, $CHMe_2{\cdot}S_2O_3Na + 3H_2O$, prepared by a method analogous to that above described, forms crystalline scales which are very soluble in water and hot alcohol, sparingly so in cold alcohol. The aqueous solution gives white precipitates with silver nitrate, and mercuric chloride, and, when concentrated, with barium chloride. The *barium* salt, $(CHMe_2S_2O_3)_2Ba + 2H_2O$, separates from its hot aqueous solution in splendid needles or laminæ.

Sodium ethylene thiosulphate, $C_2H_2(S_2O_3Na)_2$, prepared from ethylene chloride, crystallises in scales very soluble in water and in boiling alcohol. The barium salt crystallises in large, lustrous plates.

Sodium hydroxyethyl thiosulphate, $C_2H_4(OH){\cdot}S_2O_3Na$, is obtained by the action of ethylene chlorhydrin on sodium thiosulphate. It crystallises in small, brilliant needles, and is very soluble in hot water and alcohol. Its aqueous solution is decomposed by boiling, and gives a white precipitate with mercuric chloride; with silver nitrate solution no precipitate is obtained in the cold, but on warming the *silver* salt separates in crystalline laminæ.

Barium acetothiosulphate, $CH_2<\begin{matrix}COO\\S_2O_3\end{matrix}>Ba + 2H_2O$, prepared from sodium thiosulphate and sodium chloracetate, forms crystalline crusts and is fairly soluble in hot water; the solution decomposes slowly on boiling. When treated with hydrochloric acid, it yields thioglycollic acid. The *sodium* salt is very deliquescent, and will not crystallise. The *potassium* salt forms minute needles which are very soluble in water. The *silver* salt forms a white precipitate which alters when kept in the dark.

Sodium ethyl acetothiosulphate, $COOEt{\cdot}CH_2{\cdot}S_2O_3Na$, is obtained by heating ethyl monochloracetate (24 grams) dissolved in alcohol (50 grams) with sodium thiosulphate (50 grams) dissolved in water (80 grams). It crystallises from hot alcohol in beautiful monosymmetric crystals, and is very soluble in water, less so in alcohol. The aqueous solution gives white precipitates with mercuric chloride and silver nitrate. The dry salt, on distillation, yields ethyl dithioglycollate. W. J. P.

Optical Properties of Dulcitol and its Derivatives. By A. W. Crossley (*Ber.*, **25**, 2564—2565).—Diacetyldulcitol and tetracetyldulcitol are both optically inactive; the specimens stated by Bouchardat to be active were probably impure. This fact is of importance in the application of the theory of asymmetric carbon atoms to the compounds of the sugar group. J. B. T.

Disappearance of the Multirotation of Sugars in Ammoniacal Solution. By C. Schulze and B. Tollens (*Annalen*, **271**, 49—54).—Solutions of dextrose and of other sugars in concentrated ammonia do not show multirotation, the rotatory power of the freshly prepared solution being practically constant and, as a rule, rather less than that ultimately attained in aqueous solution.

The specific rotatory power of a solution of dextrose in ammonia of sp. gr. 0·924 is $[\alpha]_D = 49{\cdot}82°$ immediately after solution, that of a similar solution of xylose $[\alpha]_D = 14{\cdot}82°$, and that of a similar solution of maltose hydrate $[\alpha]_D = 126{\cdot}1°$; in all three cases, the specific rotatory power is a little lower than the constant value determined in aqueous solution. On keeping the ammoniacal solutions, the specific rotatory power gradually diminishes; in the case of the xylose solution, for example, it was found to be $[\alpha]_D = 5{\cdot}67°$ at the end of the third, and $[\alpha]_D = -5{\cdot}85°$ at the end of the fifth day.

The specific rotatory power of a solution of dextrose hydrate in 5·7 per cent. ammonia is $[\alpha]_D = 47{\cdot}24°$ about 8 minutes after solution when weaker ammonia is used, the specific rotatory power of the freshly prepared solutions gradually increases until, when 0·1 per cent. ammonia is employed, the specific rotatory power becomes normal. Even 0·01 per cent. ammonia has a very marked influence on the birotation of sugars; the specific rotatory power of a solution of dextrose hydrate in 0·01 per cent. ammonia is 49·98° 8 minutes after solution, and becomes normal at the end of 12—15 minutes longer. When the concentration of the ammonia falls to 0·001 per cent., the effect

of the solvent on the birotation of dextrose can no longer be observed with certainty.

As a result of the examination of the following compounds:—dextrose hydrate, xylose, arabinose, galactose, rhamnose, maltose hydrate, levulose, half rotatory lactose, $C_{12}H_{22}O_{11}$, and normal lactose, $C_{12}H_{22}O_{11} + H_2O$, the authors find that the values for the specific rotatory power in 0·1 per cent. ammonia, determined a few minutes after solution, are practically identical with those obtained with aqueous solutions after 20 hours; only in the case of galactose did the difference between the two values amount to almost 1°.

The rotatory power of cane sugar is not influenced by 0·1 per cent. ammonia. F. S. K.

Xylose and its Optical Properties. By C. Schulze and B. Tollens (*Annalen*, **271**, 40—46).—A large quantity of xylose was prepared from chopped wheat-straw by a method similar to that employed by Bertrand (this vol., p. 28); the yield of pure, colourless xylose amounted to about 5 per cent. of the air-dried straw. The rotatory power of the xylose was then determined in aqueous solutions of different concentration, which had been kept for 20—24 hours; the results of the observations are given in a table and are also mapped on a chart. It was found that the specific rotatory power increases continuously from 18·425° to 23·702° as the concentration increases from 9·706 to 61·737 per cent. For solutions containing up to 34·355 per cent., the specific rotatory power may be calculated by the formula $[\alpha]_D = 18·095 + 0·06986P$ (P = percentage of xylose in solution), and is represented on the chart by a straight line; for solutions containing from 34·355 to 61·737 per cent., the specific rotatory power may be calculated by the formula $[\alpha]_D = 23·089 - 0·1827P + 0·00312P^2$, and is represented on the chart by a straight line, bent slightly upwards with respect to the first line. The above observations were made at 20°, but special experiments showed that the specific rotatory power is practically constant between 15° and 20°, although above 20° the change begins to be appreciable. F. S. K.

The Pentosans of Woody Vegetable Fibre. By C. Schulze and B. Tollens (*Annalen*, **271**, 55—61; compare Abstr., 1889, 480).—The products of hydrolysis of malt which has been used for brewing are xylose and a comparatively small quantity of arabinose; the presence of mannose could not be detected. Both xylose and arabinose are only slowly decomposed by boiling 10 per cent. sulphuric acid, the former being rather less stable than the latter. Quince juice yields xylose on hydrolysis, and probably also dextrose (compare Bauer, this vol., p. 128); luffa gives about 1 per cent. of pure xylose. F. S. K.

Multirotation of Rhamnose and of the Saccharins. By W. Schnelle and B. Tollens (*Annalen*, **271**, 61—67).—A systematic examination of 10 per cent. aqueous solutions of rhamnose, $C_6H_{12}O_5 + H_2O$, at 20° has shown that the specific rotatory power of the sugar is about $[\alpha]_D = -3·11°$ immediately after solution, this value gradually becoming less until, after about $9\frac{1}{2}$ minutes, the solution is

optically inactive; the specific rotatory power then gradually increases, and after 66 minutes, a constant value of $[\alpha]_D = 8{\cdot}56°$, or $[\alpha]_D = 9{\cdot}43°$ for anhydrous rhamnose, is attained. Up to about 40 per cent., the concentration of the solution has no appreciable effect on the specific rotatory power; an increase of temperature diminishes the specific rotatory power, the diminution being about 0·035° between 6° and 20°.

Saccharin prepared from dextrose by Kiliani's method also shows multirotation; immediately after solution, the specific rotatory power is $[\alpha]_D = 94{\cdot}2°$ at 20°, but this value falls to $[\alpha]_D = 88{\cdot}7°$ after a lapse of 11 days; the specific rotatory power also decreases as the temperature rises.

The specific rotatory power of isosaccharin, from lactose, is $[\alpha]_D = 62{\cdot}97°$, that of metasaccharin $[\alpha]_D = -46{\cdot}83°$; these two compounds do not show multirotation. F. S. K.

Production of Acetic Acid from Cellulose and other Carbohydrates; Lignocellulose and Ferric Ferricyanide. By J. F. V. Isaac (*Chem. News*, **66**, 39—40).—If cotton cellulose and hydrocellulose, jute-fibre and pine wood, and sugar are acted on by alkali hydroxides within limits of temperature between 120° and 150° and 250° and 350° they yield from 7 to 10 per cent. of their weight of acetic acid; at the lower temperature, the quantity is considerable, and is increased by prolonging the action and by the addition of weak oxidising agents; potassium hydroxide produces more acetic acid than sodium hydroxide.

Jute fibre absorbs even as much as 80 per cent. of its weight of ferric ferricyanide from solutions obtained by adding potassium ferricyanide to ferric chloride, at the same time converting it into Prussian blue.

Freezing point methods of ascertaining molecular weights with Beckmann's apparatus, owing apparently to dissociation, cannot be used for solutions of cellulose acetate, benzoate, and nitrate in acetic acid. D. A. L.

Urea Oxalate. By P. H. Kirkaldy (*Chem. News*, **66**, 52).—Authorities are at variance as to the anhydrous character of urea oxalate, a view which, however, now finds support in the author's determination of carbon, hydrogen, and nitrogen, and experiments in a vacuum over sulphuric acid. D. A. L.

Propylcarbamide and Unsymmetrical Dipropylcarbamide. By F. Chancel (*Compt. rend.*, **115**, 242—243).—*Propylcarbamide* is readily obtained by the action of ammonia on the mixture of propyl iodide and propyl isocyanate resulting from the action of silver isocyanate on propyl iodide. It can be prepared even more easily by merely mixing aqueous solutions of propylamine sulphate and potassium isocyanate; part of the potassium sulphate separates at once, and the remainder can be precipitated by alcohol. The product is identical in both cases. It crystallises in long needles which melt at 107°, dissolve readily in water or alcohol, and are neutral to litmus. When heated with hydrochloric acid in sealed tubes at 160°, propyl-

carbamide yields carbonic anhydride, propylamine hydrochloride, and ammonium chloride. The nitrate and oxalate are very soluble in water, but they do not crystallise well from aqueous solutions; they are also very soluble in alcohol, from which the nitrate crystallises in slender needles.

Unsymmetrical dipropylcarbamide, $NH_2{\cdot}CO{\cdot}NPr_2$, is obtained by mixing aqueous solutions of dipropylamine sulphate and potassium isocyanate. It is very soluble in water and alcohol, and crystallises from the latter in white needles which melt at 57°; it is neutral to litmus. The normal oxalate is very soluble in water, from which it crystallises readily in needles; it is acid to litmus. The nitrate forms an uncrystallisable syrup. C. H. B.

New Method of Preparing Dimethylethylsulphine and Methyl Ethyl Sulphide. By G. Carrara (*Gazzetta*, **22**, 408—415).—Trimethylsulphine may be prepared by heating methyl sulphide (10 parts) with dry iodine (1 part) in a sealed tube at 110—120° for 24 hours; the reaction proceeds more slowly at 110°. No hydrogen iodide is produced. The product is dissolved in water and separated from unattacked methyl sulphide; the aqueous solution, after extraction with carbon bisulphide, is treated with silver chloride, filtered, evaporated on the water-bath, and trimethylsulphine platinochloride precipitated from the alcoholic ethereal solution by the addition of platinum tetrachloride. Methyl bisulphide is also produced in the reaction.

A mixture (10 parts) of ethyl and methyl sulphides in molecular proportion was heated with iodine (1 part) in a sealed tube at 120—140° for 24 hours. By treating the product as above, dimethylethylsulphine platinochloride and trimethylsulphine platinochloride were obtained. The liquid separated from the aqueous solution contained a considerable proportion of methyl ethyl sulphide, which may be obtained pure by fractional distillation.

A mixture of amyl and ethyl sulphides, when heated with iodine at 130—140°, and subsequently treated as above, yields only triethylsulphine platinochloride. Hence, it seems that there is a tendency towards the formation of a sulphine containing as few carbon atoms as possible. No ethyl bisulphide could be detected in the product.

If the additive product of methyl sulphide and bromine, Me_2SBr_2, obtained by Cahours (*Annalen*, **132**, 82), is heated with iodine at 115—120°, and afterwards treated as above, it yields trimethylsulphine platinochloride. W. J. P.

Diethyldithiophosphinic Acid. By A. W. v. Hofmann and F. Mahla (*Ber.*, **25**, 2436—2444).—When diethylphosphine (1 mol.) is added to sulphur (2 atoms), immersed in a small quantity of ether, and the mixture is kept cool, the sulphur readily dissolves, and, after a few hours, crystals separate. When the mother liquor is boiled with a slight excess of aqueous ammonia, more crystals are formed, and are collected while the liquid is hot. The solution as it cools deposits triethylphosphine sulphide, PEt_3S, whilst the cold solution, separated from these and concentrated, yields crystals of *ammonium diethyldithiophosphinate*, PEt_2SSNH_4. The latter melts at 193°, and decomposes at a

slightly higher temperature, but can be sublimed if heated rapidly. It dissolves readily in water and alcohol; its aqueous solution gives amorphous precipitates with silver, lead, and copper salts; in alcoholic solutions, crystalline precipitates are obtained. Calcium and barium salts give no precipitate; soda liberates ammonia. Bromine converts it into diethylthiophosphinic acid. Hydrochloric acid sets free *diethyldithiophosphinic acid*, PEt_2SSH, as an oil which is easily soluble in ether and alcohol, insoluble in and heavier than water, and not volatile with water vapour; it is a strong acid. The *silver salt*, PEt_2SSAg, forms white needles insoluble in cold alcohol, and stable at 100°. The *benzyl derivative*, PEt_2SSBz, melts at 54°, and is insoluble in water, but soluble in most other solvents.

The substance which first separates, after adding diethylphosphine to sulphur, crystallises from carbon bisulphide in hard, white, hexagonal prisms of adamantine lustre, and with rhombohedral faces at the extremities; it melts at 105°, and probably has the composition $PSEt_2{\cdot}S{\cdot}S{\cdot}S{\cdot}PSEt_2$. Freshly prepared ammonium sulphide converts it into ammonium diethyldithiophosphinate, with liberation of free sulphur. C. F. B.

Formaldehyde. By A. Kekulé (*Ber.*, **25**, 2435—2436).—If the gaseous formaldehyde, obtained by heating the dried solid modification, be cooled by a mixture of solid carbonic anhydride and ether, it condenses to a colourless, mobile liquid which boils at −21°, and has approximately the sp. gr. 0·9172 at −80°, and 0·8153 at −20°. At −20° it is transformed in a short time into the solid variety. In a sealed tube at the ordinary temperature the same change takes place, but so rapidly as to cause a considerable rise of temperature and a series of small explosions in the tube. C. F. B.

Preparation of Aldol and Crotonaldehyde. By W. R. Orndorff and S. B. Newbury (*Monatsh.*, **13**, 516—518; compare Abstr., 1891, 285).—To obtain a good yield, the following directions must be closely adhered to:—Aldehyde boiling at 21° is prepared by boiling paraldehyde with a drop of concentrated sulphuric acid, and leading the vapour through a long Hempel's tube packed with glass beads. 200 grams is then cooled to 0°, and gradually added to 200 grams of water at 0°, the temperature not being allowed to rise above 5°. The mixture is then cooled to 0°, and 10 grams of dry, powdered potassium carbonate added in successive small portions, care being taken that no rise of temperature takes place. After the carbonate is all dissolved, the flask is removed from the ice and water and allowed to remain for 12—18 hours in a cool place, preferably at about 10°; the liquid has then become syrupy, and slightly yellowish in colour. It is poured into a separating funnel of 1 litre capacity, and shaken for a long time with an equal volume of ether; the aqueous extract is removed, shaken with half its volume of ether, separated from the same, just neutralised with dilute hydrochloric acid, and again shaken with half its volume of ether. The ether extracts are united, and the ether distilled off; the residue amounts to 90 per cent. of the aldehyde employed, and consists chiefly of aldol, mixed with ether,

aldehyde, paraldehyde, and water. To obtain the aldol, this residue is distilled under diminished pressure. From 100 grams of aldehyde 50 grams of aldol boiling at 90—110° under 40 mm. pressure were thus obtained.

To prepare crotonaldehyde, the residue should be at once distilled under atmospheric pressure over a bare flame, a short Hempel's tube filled with glass beads being used, and the thermometer not being allowed to indicate a temperature higher than 100°. To the distillate calcium chloride is added until the water in it is saturated, and the whole is poured into a separating funnel and shaken, in order to completely remove the water and aldol. The aqueous solution is separated from the crotonaldehyde, which after being dried by boiling it with calcium chloride in a reflux apparatus, is fractionated in a distilling flask, the neck of which is filled with glass beads. From 200 grams of aldehyde, 48—50 grams of pure crotonaldehyde, boiling at 104—105°, were thus obtained. C. F. B.

Preparation of Crotonaldehyde. By A. Lieben (*Monatsh.*, **13**, 519—521; see also preceding abstract).—50 c.c. of acetaldehyde are placed in a sealed tube with 10 c.c. of a 28 per cent. aqueous solution of sodium acetate; the tube is shaken, and then heated for about 36 hours in a horizontal position at 95—100°. The contents have then contracted to about seven-eighths of their original volume, and the upper layer should have a slight, but only a slight, yellowish tinge. The contents, after being distilled on the water-bath to remove acetaldehyde, are distilled with steam, when oily drops of crotonaldehyde and other substances come over. These are fractionated in an atmosphere of carbonic anhydride, preferably under reduced pressure, so that the temperature does not exceed 130°. From 100 parts of acetaldehyde, 30 parts were recovered, and 42 parts obtained volatile with steam; of these, 21 were crotonaldehyde. C. F. B.

Glycolaldehyde. By E. Fischer and K. Landsteiner (*Ber.*, **25**, 2549—2554).—Bromacetal is readily prepared by the action of bromine (136 grams) on acetal (100 grams) in presence of recently precipitated calcium carbonate (42 grams), a product being obtained which boils at 164—172°; the yield is 50 per cent. The bromacetal is then heated with the calculated quantity of anhydrous oxalic acid at 150°, and the distillate fractionated; the portion boiling at 80—105° consists of bromaldehyde together with water and some impurities; this mixture forms a colourless, viscid liquid, which is soluble in water, and readily reduces alkaline copper solution; the vapour rapidly attacks the eyes. On treatment with phenylhydrazine in aqueous solution, an insoluble compound is formed which has not been further investigated.

Glycolaldehyde is prepared from the preceding impure bromo-compound by treatment with barium hydroxide in aqueous solution at 0°; the aldehyde readily reduces alkaline copper solution at ordinary temperatures, and turns yellow on warming with alkalis; it is insoluble in ether, and is only very slightly volatile with steam either

at ordinary pressures or in a vacuum. On heating the aldehyde with phenylhydrazine acetate at 40°, glyoxalphenylosazone is formed.

Glycolaldehyde, like ordinary sugars, is oxidised to glycollic acid by the action of bromine water. On treating the aqueous solution of glycolaldehyde (see above) with soda, in such quantity that the liquid contains 1 per cent., it undergoes polymerisation; after remaining 15 hours at 0°, the liquid no longer reduces alkaline copper solutions at ordinary temperatures; and on heating with phenylhydrazine acetate for 8—10 hours, a compound is deposited which melts at 166—168°, and appears to be identical with phenylerythrosazone; attempts to regenerate the sugar from this compound were unsuccessful.

With the synthetic formation of tetrose, a complete series of sugars as far as the nonoses is known, and all can be prepared synthetically with the exception of the pentoses. J. B. T.

Chloracetone. By J. Tcherniac (*Ber.*, **25**, 2629—2632; compare following abstracts).—When crude thiocyanacetone is distilled with water in a vacuum, an oil passes over, which can be only partially separated into two substances by fractional distillation. On treating it with hydrogen sodium sulphite solution, a considerable proportion dissolves, and when recovered by distilling the aqueous solution with the calculated quantity of calcium chloride, is found to be pure dichloracetone; this has a slightly pungent but not ethereal odour, more like that of chloral than of chloracetone. It thus differs from the descriptions given by Chlöez (*Ann. Chim. Phys.* [6], **9**, 165), and by Borsche and Fittig (*Annalen*, **133**, 111). The oil insoluble in the sulphite solution, on extraction with ether and evaporation of the ethereal solution, yields a mixture boiling at 123—125°. Its approximate composition is C_5H_9ClO, and it seems to be the constituent which gave to Borsche and Fittig's chloracetone its pleasant ethereal odour.

These two components of the oil must have been originally present as impurities in the chloracetone used in the preparation of the thiocyanacetone; it would therefore seem that chloracetone obtained by Barbaglia's method contains at least 15 per cent. of foreign matter. Halogen determinations in chloracetone prepared in this way, however, agree with the formula C_3H_5ClO. W. J. P.

Thiocyanacetone. By J. Tcherniac (*Ber.*, **25**, 2607—2620).—Tcherniac and Hellon (Abstr., 1883, 653) obtained an oil which they considered to be thiocyanacetone by the action of barium thiocyanate on chloracetone. Hantzsch and Weber (Abstr., 1888, 256), by slightly modifying their method of preparation, obtained only a crystalline substance which they termed methyloxythiazole. Later, however, Arapides (Abstr., 1889, 413) stated that thiocyanacetone is produced in the reaction, but cannot be isolated in a pure state, as in presence of water it is slowly converted into its isomeride, methyloxythiazole.

Thiocyanacetone dissolves in aqueous hydrogen potassium sulphite with considerable development of heat, thus indicating its ketonic

nature. The author finds that the method given by Arapides for its preparation is not only costly but yields an impure product; he was quite unable to effect the conversion of thiocyanacetone into methyloxythiazole, as described by Arapides. Thiocyanacetone cannot be converted into the thiazole by heating its aqueous solution on the water-bath with dilute hydrochloric acid; the thiazole is also but slightly soluble (12 per cent. at 14°) in the acetone.

Hantzsch and Weber, in preparing methyloxythiazole, added dry sodium carbonate to the solution, and then obtained no thiocyanacetone; the author finds that the acetone is converted into methyloxythiazole not only by sodium carbonate, but by such slightly alkaline substances as borax, normal sulphites, and zinc oxide. This affords an explanation of Hantzsch and Weber's erroneous statement that no thiocyanacetone is formed.

The author considers that he has proved that the oil obtained by himself and Hellon is the true thiocyanacetone, and under normal conditions contains no methyloxythiazole. W. J. P.

Preparation and Estimation of Thiocyanacetone. By J. Tcherniac (*Ber.*, **25**, 2621—2626).—The author has devised a thermoanalytical method of estimating thiocyanacetone. The heat developed on treating an aqueous solution of this substance with normal sodium carbonate solution is directly proportional to the amount of the acetone present. The estimation is carried out in a Beckmann's apparatus for cryoscopic determinations, and is performed in much the same way as those determinations.

The author prepares thiocyanacetone as follows:—Equivalent quantities of chloracetone and crystallised barium thiocyanate are shaken together in a thick flask containing some glass marbles to break up the mass. The odour of chloracetone disappears after 6—15 hours, when the reaction is complete. The product is extracted thrice with ether, the ethereal solution washed with a little water, and distilled at 40—50°. A slow stream of carbonic anhydride is passed through the residue, kept under a low atmospheric pressure at 40—50°; after evaporating off the water by this means, the residual oil contains about 98·18 per cent. of thiocyanacetone. It can be further purified by shaking its saturated aqueous solution in the cold with animal charcoal (1 per cent.); on extracting with ether, and evaporating the ethereal solution in a vacuum over sulphuric acid, a product containing 99·18 per cent. of thiocyanacetone is obtained. On distilling the aqueous solution of this under reduced pressure in a stream of carbonic anhydride at 40—50°, and evaporating the ethereal extract of the distillate in a vacuum over sulphuric acid, a still purer product is got.

Thiocyanacetone, prepared as above, is a slightly coloured, strongly refractive oil, which darkens very slowly when kept in the dark. Its sp. gr. is 1·200 at 0°/4° and 1·180 at 20°/4°. It dissolves in 14·3 parts of water at 15°, and is very soluble in ether, benzene, and chloroform, sparingly so in light petroleum and carbon bisulphide; it is fairly stable towards dilute acids. W. J. P.

Stereometric Relations of Erucic Acid and Brassidic Acid. By A. Holt (*Ber.*, **25**, 2667—2671).—In a previous paper (this vol., p. 812), the author has shown that the bromo- and iodo-additive products of behenolic acid are reconverted into behenolic acid by the action of sodium amalgam, and are therefore to be considered as derivatives of brassidic acid. The present paper deals with the chloro-additive compounds.

Dichlorobrassidic Acid.—When a chloroform solution of behenolic acid cooled with ice and salt is treated with chlorine, 1 mol. of chlorine is absorbed, and a viscid, pale-yellow oil is obtained, which gives numbers corresponding with the formula of dichlorobrassidic acid. On treating this product with sodium amalgam, it is found to be a mixture, for it yields a small quantity of behenolic acid, an oil free from chlorine, and a small quantity of behenic acid (m. p. 76°). Dichlorobrassidic acid is, however, easily obtained in a state of purity by boiling the corresponding dibromo-componnd with mercuric chloride (1 mol.) in alcoholic solution. It is a viscid, bright yellow oil, is somewhat sparingly soluble in cold alcohol, easily so in warm alcohol and other organic solvents, and when treated with sodium amalgam yields 90 per cent. of the theoretical quantity of behenolic acid.

The *tetrachloride of behenolic acid* cannot be obtained by the direct action of chlorine on behenolic acid; but is easily obtained by boiling the tetrabromide with mercuric chloride (2 mols.). It separates from alcohol as an oil, but soon solidifies in beautiful, long needles; it melts at 41°, and when treated with sodium amalgam is entirely converted into behenolic acid.

Behenolic acid dissolves in pure concentrated sulphuric acid to a pale-brown, clear solution, which yields a small quantity of precipitate after a time, and darkens. By pouring the product into water, a hydroxy-acid, $C_{22}H_{41}O_2{\cdot}OH$, is obtained; this crystallises from alcohol as a white powder, melts at 83°, and is identical with the acid obtained by the action of concentrated hydrochloric acid on behenolic acid.

Behenolic anilide, $C_{21}H_{39}{\cdot}CO{\cdot}NHPh$, is obtained by heating behenolic acid with excess of aniline for four hours at 220°, and extracting the product with very dilute hydrochloric acid. It separates from alcohol as a colourless, voluminous, crystalline mass, melts at 73°, is easily resolved into its components by halogen acids, is fairly stable towards potash, and when boiled with alcoholic potash for 10 hours yields aniline and behenolic acid.

Behenolic phenylhydrazide, $C_{21}H_{39}{\cdot}CO{\cdot}NH{\cdot}NHPh$, is obtained by warming molecular proportions of behenolic acid and phenylhydrazine at 140—145°. It crystallises from alcohol in small, colourless needles, melts at 86·5°, is somewhat sparingly soluble in cold alcohol, gives a mirror with alcoholic ammoniacal silver nitrate, and dissolves in concentrated sulphuric acid to a colourless solution, which turns dark-red on the addition of potassium dichromate. When oxidised with copper acetate in alcoholic solution, it yields behenolic acid and *behenolic diphenylhydrazide*, $C_{21}H_{39}{\cdot}CO{\cdot}NH{\cdot}NPh_2$; this melts at 104—105°, and with sulphuric acid gives a bluish-green solution which turns pure blue on the addition of potassium dichromate.

The author has also prepared the phenylhydrazides of erucic, brassidic, and stearolic acids, by heating the acids with phenylhydrazine in molecular proportion at 140°.

Stearolic phenylhydrazide crystallises in lustrous, white needles, melts at 81·5—82°, and with sulphuric acid gives a bright yellow solution, which changes to rose-red on the addition of potassium dichromate.

Erucic phenylhydrazide is a white, crystalline powder, melts at 82°, and gives a colourless solution with sulphuric acid, which on the addition of potassium dichromate changes to blood-red and then brown.

Brassidic phenylhydrazide is a white, crystalline mass, melts at 95°, and gives the same colour reactions with sulphuric acid as the preceding compound. E. C. R.

Constitution of Ethyl Sodacetoacetate. By A. Michael (*J. pr. Chem.* [2], **46**, 189—208).—The author continues his criticism (this vol., p. 1178) of Nef's paper on ethyl acetoacetate (this vol., p. 140). From the fact that ethyl copper acetoacetate and ethyl lead acetoacetate do not react so easily with ethyl iodide as ethyl sodacetoacetate does, Nef argues that there is no direct substitution of the sodium by the ethyl in the latter reaction, and in support of this he quotes what he supposes to be facts concerning the greater ease with which copper, lead, or mercury phenol, and the salts of these metals, are attacked by ethyl iodide than are the corresponding sodium compounds. The author asserts that this difference is entirely imaginary. According to Nef's hypothesis, an intermediate compound containing the group :CI·ONa is formed when ethyl iodide and ethyl sodacetoacetate react. The iodine atom in this group is then supposed to leave the molecule in company with the hydrogen atom of the next group; the group CONa remains, and subsequently reacts with the evolved hydrogen iodide, forming the group COH. This is contrary to all our knowledge concerning compounds which contain both hydroxyl and halogen atoms attached to the same carbon atom; such compounds lose the hydroxyl hydrogen and halogen as hydrogen halide with the greatest ease, and the same course of change may surely be expected when sodoxyl replaces hydroxyl. Nor can Nef's experiments be held to fully confirm his conclusion that the more negative the group introduced into the molecule of ethyl acetoacetate the larger will be the proportion of di-substitution product formed in subsequent reactions (this vol., p. 141). For inasmuch as the reaction between ethyl chlorocarbonate and ethyl sodacetoacetate results in the production of 7 parts of di- and 2 parts of mono-derivative (ethyl acetylmalonate and ethyl acetylcarbintricarboxylate, this vol., p. 145), acetyl must be, according to Nef, more negative than the group COOEt, yet the reaction between ethyl sodacetoacetate and acetic chloride yields much ethyl acetylacetoacetate and only a little ethyl diacetylacetoacetate (ethyl triacetylacetate, this vol., p. 145). The statement that ethyl ethylacetoacetate is not reduced by treatment with sodium in ethereal solution is incorrect; the author found that the quantity of hydrogen evolved by the reaction is far short of

the theoretical quantity, and when the liquid was subsequently examined undoubted evidence of the presence of unsaturated acids was obtained.

These are the main points of the critical portion of the paper. The theoretical considerations with which it concludes can only be appreciated by reference to the original. A. G. B.

Action of Phenylhydrazine and of Hydroxylamine on Dehydrodiacetyllevulinic Acid. By G. MAGNANINI and M. SCHEIDT (*Gazzetta*, **22**, 436—448).—An *oxime* of dehydrodiacetyllevulinic acid, $C_9H_{11}NO_4$, is obtained when a mixture of the acid (1 gram), hydroxylamine hydrochloride (0·70 gram), and sodium carbonate (1·5 grams) is dissolved in water and left for 24 hours at the ordinary temperature. The oxime is deposited on adding hydrochloric acid, and crystallises from boiling alcohol in colourless needles which melt with decomposition at 198—199°. It is insoluble in water, very soluble in alcohol, and sparingly so in chloroform, benzene, and acetic acid; it decomposes on boiling with water or aqueous alcohol..

Dehydrodiacetyllevulinic acid yields a *hydrazone*, $C_{15}H_{16}N_2O_3$, when heated with phenylhydrazine in acetic acid solution. It forms matted white needles, melts at 185—187°, and is soluble in alcohol and ether, sparingly so in benzene, and insoluble in water. It must be crystallised from absolute alcohol, as it is partially decomposed if heated in presence of water. On heating the hydrazone (1 gram) in a sealed tube with water (25 grams) for 3—4 hours at 150—160°, small, monosymmetric prisms ($a : b : c = 3·4969 ; 1 : 3·8391$, $\beta = 52° 11'$) are obtained, which have the composition $C_{14}H_{16}N_2O$, and melt at 137°. Both this substance and the hydrazone give normal molecular weights by the cryoscopic method.

Attempts to introduce a second phenylhydrazine residue into dehydrodiacetyllevulinic acid were unsuccessful. When the acid is heated with phenylhydrazine, water, and acetic acid at 200°, a substance of the composition $C_{14}H_{16}N_2O$ is obtained.

On heating dehydrodiacetyllevulinic acid in a sealed tube with ammonia at 100°, a substance of the composition $C_8H_{11}NO$ is formed; this, on treatment with benzaldehyde, gives a compound which has the composition $C_{15}H_{15}NO$, and crystallises in small, orthorhombic prisms ($a : b : c = 2·3333 : 1 : 1·9301$). It is soluble in alcohol and chloroform, less so in acetic acid, and insoluble in water; it melts at 208·5°, and gives a normal molecular weight by the cryoscopic method. The compound $C_8H_{11}NO$ gives a chloride and a platinochloride, and readily combines with bromine; when either this substance or the compound obtained by treating it with benzaldehyde is distilled with zinc-dust, oils are obtained which have the properties of pyrrolines. These two substances are now under investigation.

The authors have determined the electrical conductivity of dehydrodiacetyllevulinic acid, $K = 0·00682$. If the solution is kept, the coefficient changes rapidly, owing to decomposition of the acid.

W. J. P.

Azodicarboxylic Acid. By J. THIELE (*Annalen*, **271**, 127—136).—Hydrazodicarbonamide (compare this vol., p. 1295) is best pre-

pared by dissolving hydrazine sulphate (130 grams) and crystallised sodium acetate (136 grams) in warm water (about 1·3 litres), and adding to the cold mixture a concentrated solution of potassium cyanate (180 grams). After a short time, the separation of hydrazodicarbonamide commences, and the solution, which would otherwise become feebly alkaline, is kept slightly acid by the addition of acetic acid. After about two hours time, a further quantity (25—30 grams) of potassium cyanate is added, and the solution allowed to remain over night; the colourless crystalline product is then separated by filtration, washed, and dried. The yield is 103 grams, or 87 per cent. of the theoretical.

Hydrazodicarbonamide seems not to be acted on by moderately concentrated (1 : 1) potash in the cold; it is soluble in warm potash, yielding as a rule a turbid solution, from which it is precipitated unchanged on adding water. Azodicarbonamide (*loc. cit.*) can be easily obtained by triturating the finely-divided hydrazo-compound (10 grams) with water (1 litre), heating to boiling, and then adding a solution of potassium dichromate (16 grams) in water (60 c.c.) and sulphuric acid (15 c.c.); an energetic reaction takes place, the mixture darkens in colour, and the whole of the hydrazo-compound passes into solution. The solution is then cooled to 0° as quickly as possible, and the azodicarbonamide, which is precipitated as an orange-red powder, separated by filtration, washed, and dried. The yield is 70 per cent. (7 grams). Azodicarbonamide is decomposed by boiling sodium carbonate, yielding nitrogen, carbonic anhydride, ammonia, and hydrazodicarbonamide.

Potassium azodicarboxylate, COOK·N:N·COOK, is formed with evolution of ammonia when azodicarbonamide is triturated with ice-cold, moderately concentrated (1 : 1) potash. It is a yellow powder, stable in the air, but decomposed by water, in which it dissolves freely with a yellow coloration. The dry substance decomposes slowly at 100°, and explodes at a slightly higher temperature, yielding in both cases potassium carbonate, nitrogen, and carbonic oxide. It gives Liebermann's reaction, but the colorations are much less intense than in the case of a nitroso-compound.

Barium azodicarboxylate, $C_2N_2O_4Ba$, can be obtained by adding a solution of barium chloride, which has been saturated with barium hydroxide, to a solution of the potassium salt; it is a light yellow powder insoluble in water, by which it is quickly decomposed.

When potassium azodicarbonamide is treated with water at the ordinary temperature, a vigorous evolution of nitrogen and carbonic anhydride takes place and a yellow solution is obtained; after a very short time, the solution becomes colourless, and then contains hydrazine and potassium carbonate. The decomposition of the barium salt takes place more slowly, but in a similar manner. The aqueous solution of the potassium salt is much more stable in presence of caustic alkalis, and under these conditions the yellow colour does not disappear for some minutes even on boiling.

All attempts to prepare diimide, NH:NH, from the salts of azodicarboxylic acid were unsuccessful, and it would seem that this compound is incapable of existence. F. S. K.

Copper Oxalate and Cuprammonium Oxalate. By K. Seubert and G. Rauter (*Ber.*, **25**, 2821—2825).—Copper oxalate was prepared by precipitating a solution of copper sulphate with sodium oxalate, and purified by dissolving the finely-divided precipitate in ammonia and pouring the solution into dilute acetic acid. When dried in the air, it contains a little less than 1 mol. H_2O; when dried over sulphuric acid, or by heating at 80—90°, it has the formula $CuC_2O_4 + \frac{1}{2}H_2O$. When dried at 95—105°, it contains $\frac{1}{4}$ mol. water, which cannot be driven off without decomposing the salt.

Cuprammonium oxalate is obtained by the evaporation of a solution of copper oxalate in excess of ammonia. It is decomposed by water at the ordinary temperature with separation of cupric oxalate, and, on boiling, with separation of black cupric oxide. When exposed to air, it decomposes, and all the water and part of the ammonia are given off. The loss in weight is 20·33 per cent. On analysis, the salt gave numbers agreeing with those required by the formula $CuC_2O_4,2NH_3 + 2H_2O$.

A compound of cupric oxalate and pyridine is obtained by rubbing dry copper oxalate with pyridine, and is a crystalline powder. It smells strongly of pyridine, and loses pyridine on exposure to air or on gently heating. When heated at 130°, it decomposes, and when heated strongly, burns with a sooty, green-bordered, yellow flame. The salt has the composition $CuC_2O_4,2C_5NH_5$. E. C. R.

Inactive Ethyl Malate. By W. Wislicenus (*Ber.*, **25**, 2448—2449).—When ethyl oxalacetate, $COOEt{\cdot}CO{\cdot}CH_2{\cdot}COOEt$, is reduced rapidly with sodium amalgam in a cooled acid solution, both inactive malic acid and its ethyl salt are formed. By nearly neutralising the product with soda and extracting with ether, the ethyl salt is removed, and the acid remains behind. The yield of the ethyl salt is about half the amount of the oxalacetate employed. Ethyl malate boils at 150—152° under 27 mm. pressure, and, unlike the acid itself, boils without decomposition under atmospheric pressure, at 255°. It has sp. gr. 1·124 at 21°/4°, and gives an acid reaction with moistened litmus paper. When hydrolysed with soda, it yields the sodium salt as a white, deliquescent, crystalline powder. C. F B.

Polarisation Phenomena of Rhamnonic Acid and Rhamnolactone. By W. Schnelle and B. Tollens (*Annalen*, **271**, 68—74; compare Abstr., 1891, 43).—The specific rotatory power of rhamnonic acid, in a freshly-prepared solution, obtained by decomposing strontium rhamnonate with hydrochloric acid, is about $[\alpha]_D = -7{\cdot}67°$; after keeping for $3\frac{1}{2}$ hours, the specific rotatory power has increased to $[\alpha]_D = -29{\cdot}21°$, at which value it remains; if, however, the solution is heated at 100° for half an hour, the specific rotatory power becomes $[\alpha]_D = -34{\cdot}30°$, the acid being now almost completely converted into the lactone; the specific rotatory power of the solution of the lactone then slowly decreases, owing to partial reconversion into the acid, and after three days' time it has again fallen to $[\alpha]_D = -30{\cdot}12°$. F. S. K.

Polarisation Phenomena of Gluconic Acid and Gluconolactone. By W. Schnelle and B. Tollens (*Annalen*, **271**, 74—80; compare Abstr., 1891, 43, and Fischer, Abstr., 1890, 1389).—The specific rotatory power of the lactone of gluconic acid is $[\alpha]_D = 61{\cdot}59°$ 10 minutes after solution, but this value gradually diminishes, becoming constant at $[\alpha]_D = 20°$ after about a month and a half; from these results, and from those obtained with gluconic acid (*loc. cit.*), it follows that in aqueous solution the lactone is slowly converted into the acid, and *vice versâ*, until a condition of equilibrium is established.

If, in preparing gluconic acid from dextrose, only the theoretical quantity of bromine is employed, there is formed a crystalline lactone, which melts at 110—115°, and seems to have the composition $C_{12}H_{22}O_{11}$ or $C_{12}H_{20}O_{11}$. This substance loses approximately $1\frac{1}{2}$ mols. H_2O at 100°; its specific rotatory power is $[\alpha]_D = 39{\cdot}07°$ immediately after solution, but gradually falls to $[\alpha]_D = 14{\cdot}84°$. F. S. K.

Polarisation Phenomena of Galactonic Acid and Galactonolactone. By W. Schnelle and B. Tollens (*Annalen*, **271**, 81—86; compare Abstr., 1891, 43).—Calcium galactonate, $(C_6H_{11}O_7)_2Ca + 5H_2O$, loses 4 mols. H_2O on long exposure to the air, and becomes anhydrous when gradually heated in a stream of dry air; it crystallises in microscopic plates, is only sparingly soluble (0·76 part in 100) in water at 15°, and its specific rotatory power is approximately $[\alpha]_D = 2{\cdot}85°$. When the calcium salt is decomposed with oxalic acid, and the filtered solution evaporated over sulphuric acid, a crystalline compound melting at 123—125° is gradually deposited; if, however, the filtered solution is concentrated to a syrup, then taken up with warm alcohol, and evaporated over sulphuric acid, the lactone *hydrate*, $C_6H_{10}O_6 + H_2O$, crystallises from the solution; this compound melts at 64—65°, and loses its water at 85°, the anhydrous lactone melting at 90—92°. The specific rotatory power of the lactone hydrate is approximately $[\alpha]_D = -65°$, 10 minutes after solution; this value diminishes slightly on keeping the solution for a long time. F. S. K.

"Isarabic Acid." By M. Conrad (*Ber.*, **25**, 2446—2448).—The formation of this acid, by the action of ferrous sulphate on tartaric acid, is not due, as Ballo thought (Abstr., 1889, 693), to the reducing action of the former, but rather to its dehydrating action (*cf.* Scheibler, this vol., p. 1180). Equal weights of tartaric acid and ferrous sulphate were dissolved in twice the weight of water, and heated on the water-bath for 15 hours. The solution was filtered, concentrated to a small bulk, and extracted with alcohol. The extract was neutralised with barium carbonate, filtered, evaporated to dryness, dissolved in water, and converted, by means of potassium carbonate, into the potassium salt of isarabic acid. The concentrated solution of the latter, when treated with excess of acetic acid and alcohol, gave a precipitate of potassium hydrogen tartrate, and potassium hydrogen isarabate remained in solution. If, however, the latter is precipitated with lead acetate, the precipitate decomposed with hydrogen

sulphide, and the solution filtered and concentrated, tartaric acid crystallises out; if the aqueous solution of the potassium salt is heated for a few minutes only with aqueous potash, and then acidified with acetic acid, potassium hydrogen tartrate separates out. This very ready conversion of isarabic into tartaric acid renders it improbable that the former is formed from the latter by reduction.

C. F. B.

Thetincarboxylic Acids. By A. Delisle (*Ber.*, **25**, 2450—2453).—Dimethylthetin-mono- and -di-carboxylic acids may easily be prepared by digesting a mixtnre of sodium thiodiacetate or methyl thioacetate with sodium chloracetate, in molecular proportion, on the water-bath, and adding hydrochloric acid and ether to the product.

Dimethylthetindicarboxylic acid, $CO<\overset{O}{\underset{CH_2}{—}}>S(CH_2\cdot COOH)_2$, forms small, colourless, ill-defined, lustrous needles, melts with decomposition at 157—158°, dissolves fairly readily in hot, very sparingly in cold water, and not at all in most organic solvents. It dissolves in concentrated hydrochloric acid, forming the compound $C_6H_8O_6S,HCl$, which, however, easily splits into chloracetic and thiodiacetic acids. When reduced with sodium amalgam, it yields acetic and thiodiacetic acids. When distilled, it breaks up into methyl sulphide, methyl methylthioacetate, and methyl thiodiacetate. The *silver salt*, $C_6H_6O_6SAg_2$, crystallises in needles or plates, and is very stable. The *barium salt*, $C_6H_6H_6SBa$, crystallises in long, radiating, silky needles. The *sodium salt*, $C_6H_6O_6SNa_2 + 3H_2O$, crystallises in brilliant, prismatic needles, readily soluble in water, but insoluble in alcohol. No acid salts have been prepared; salts of alkaline reaction, however, derived from the acid $OH\cdot S(CH_2\cdot COOH)_3$ have been obtained.

Dimethylthetincarboxylic acid, $CO<\overset{O}{\underset{CH_2}{—}}>SMe\cdot CH_2\cdot COOH$, crystallises in lustrous, slightly opalescent, cubical crystals, and melts with decomposition at 150°.

Pyridinebetaïne may also be obtained by heating pyridine with sodium chloracetate; it forms large, rhomboidal tables.

C. F. B.

Formation of Furfuraldehyde from Glycuronic Acid Derivatives and from Albumin. By A. Günther, G. de Chalmot, and B. Tollens (*Ber.*, **25**, 2569—2572).—Glycuronic anhydride, euxanthic acid, and urochloralic acid, all yield furfuraldehyde on distillation with hydrochloric acid; the proportion of furfuraldehyde from glycuronic acid is almost the same as that obtained from arabinose and xylose.

Normal urine yields a trace of furfuraldehyde on distillation with hydrochloric acid, as also does caseïn and dried horseflesh, which has been freed from carbohydrates.

J. B. T.

Oximes of Furfuraldehyde, Thiophenaldehyde, and Œnanthaldehyde. By H. Goldschmidt and E. Zanoli (*Ber.*, **25**, 2573—2596).—Furfursynaldoxime, $\overset{C_4OH_3\cdot C\cdot H}{\underset{N\cdot OH}{\|}}$ (m. p. 89°), is readily prepared

by the action of hydroxylamine on furfuraldehyde, or by treatment of the antialdoxime (see below) with hydrogen chloride in ethereal solution; its molecular weight determined by the boiling point method agrees with the above formula. On treating the aldoxime with methyl iodide and sodium methoxide in methyl alcoholic solution, a *methyl derivative* is obtained which crystallises from ether with 1 mol. H_2O in flat, lustrous, transparent needles melting at 56°; after remaining in a vacuum over sulphuric acid for some days, the *anhydrous compound*, $C_4OH_3{\cdot}CH{<}\overset{O}{\underset{NMe}{|}}$, is formed; this crystallises from chloroform, benzene, or ether in large, quadratic, transparent plates, melts at 91—92°, and combines directly with hydrogen chloride; on heating with dilute sulphuric acid, it is resolved into furfuraldehyde and β-methylhydroxylamine.

Two benzylfurfuraldoximes have been described by Werner (Abstr., 1890, 1266) melting at 88° and 65° respectively; the second of these proves to be a hydrate of the first, into which it is converted by remaining for some time over sulphuric acid in a vacuum.

Two isomeric additive compounds are formed by the action of phenyl cyanate on furfursynaldoxime in ethereal solution; the first is deposited in pale yellow, transparent, microscopic, oblique prisms which soften at 65°, melt at 72° with decomposition, and yield diphenylcarbamide, aniline, furfursynaldoxime, and furfurcarboxylic acid on treatment with soda. The second compound is obtained with more concentrated solutions at somewhat higher temperatures, and crystallises in colourless, hexagonal plates melting at 83°; after repeated crystallisation, it is deposited in lustrous, thick prisms which melt at 98°, and yields the same decomposition products with soda as the yellow substance, but on boiling with alcohol or on treatment with acetic chloride at ordinary temperatures, carbanilidofurfurantialdoxime, $\overset{C_4OH_3{\cdot}C{\cdot}H}{\underset{NHPh{\cdot}COO{\cdot}N}{\|}}$ (m. p. 138°), is formed.

Carboparatoluidofurfursynaldoxime, $\overset{C_4H_3O{\cdot}C{\cdot}H}{\underset{N{\cdot}O{\cdot}CONH{\cdot}C_6H_4Me'}{\|}}$ is prepared from the aldoxime and paratolyl cyanate, and is deposited in pale yellow, transparent plates melting at 79—80° with decomposition; with soda, it decomposes in a similar manner to the phenyl derivative. On recrystallisation from warm ether, a compound is deposited in crystalline plates which melt at 96°. The *orthotoluido-derivative* closely resembles the para-compound, but is more readily soluble, and melts at 50° without decomposition; on crystallisation from absolute alcohol, colourless needles are obtained which melt at 65°.

Furfurantialdoxime, $\overset{C_4OH_3{\cdot}C{\cdot}H}{\underset{HO{\cdot}N}{\|}}$, is prepared by mixing sodium hydroxide (31·4 grams) in water (200 c.c.) with hydroxylamine hydrochloride (11 grams) dissolved in water (50 c.c.); the solution is well cooled, and to it is gradually added furfuraldehyde (10 grams); carbonic anhydride is now passed through it until the soda is neutralised, and the liquid is then extracted with ether; the ether is evaporated, and the residue, after repeated crystallisation from light

petroleum, is obtained in long, colourless, strongly-refractive needles melting at 73—74°. Molecular weight determinations by the boiling point method confirm the above formula. The compound is soluble in ether, benzene, alcohol, and water; on heating with dilute sulphuric acid, it is resolved into its constituents. The isomeric furfuraldoxime (m. p. 49—56°) described by Oderheimer consists of a mixture of furfursynaldoxime and antialdoxime, as is shown by its action on phenyl cyanate. With orthotolyl or paratolyl cyanate, carbotoluidofurfursynaldoximes (see below) are formed, the anti-derivatives being apparently incapable of separate existence.

Benzantialdoxime, on treatment with paratolyl cyanate in ethereal or benzene solution, both at ordinary temperatures and on warming, yields *carboparatoluidobenzantialdoxime*, $\begin{matrix}C_6H_5\cdot C\cdot H\\ \|\\ C_6H_4Me\cdot NH\cdot COO\cdot N\end{matrix}$, which crystallises from benzene in colourless needles and melts at 121°. The corresponding *benzsynaldoxime derivative* melts at 74—76°, and on recrystallisation from ether is converted into a compound which melts at 88—89°.

Furfurantialdoxime is partially converted into the synaldoxime by the action of acetic anhydride; on treatment with methyl iodide in the manner above described and distilling with steam, a product is isolated which boils at 150—168°, and appears to be an impure *methyl* ether; methylfurfursynaldoxime is also produced in considerable quantity.

Thiophenaldoximes.—Thiophensynaldoxime melts at 133°, instead of 128°, as stated by V. Meyer. On treatment with methyl iodide, it yields *methylthiophensynaldoxime*, $C_4SH_3\cdot CH<\begin{matrix}NMe\\ |\\ O\end{matrix}$, which crystallises from benzene in thin, transparent plates melting at 120°. It combines directly with hydrogen chloride, and, on boiling with dilute sulphuric acid, is resolved into thiophenaldehyde and β-methylhydroxylamine, whilst heating it with hydriodic acid at 100° gives rise to methylamine. Thiophensynaldoxime combines with phenyl cyanate in ethereal solution to form *carbanilidothiophensynaldoxime*, $\begin{matrix}C_4H_3S\cdot C\cdot H\\ \|\\ N\cdot O\cdot CO\cdot NHPh\end{matrix}$, which is deposited in yellow, transparent needles melting at 69—70° with decomposition. On recrystallisation from alcohol, colourless needles are obtained which melt at 77° with evolution of gas, and are converted into carbanilidothiophenantialdoxime (see below) on further heating with alcohol.

Thiophenantialdoxime, $\begin{matrix}C_4SH_3\cdot C\cdot H\\ \|\\ HO\cdot N\end{matrix}$, is obtained as a slightly coloured, viscid liquid by treating thiophenaldehyde (1·9 grams) with a mixture of hydroxylamine hydrochloride (2 grams) and sodium hydroxide (4 grams) in aqueous solution, hydrogen sodium carbonate (9 grams) is then added, and the liquid extracted with ether; the same compound is also obtained by the action of soda on the carbanilido-derivative (see above); it is slowly changed, at ordinary temperatures, into the syn-modification, whilst with hydrogen chloride the change is immediate.

Carbanilidothiophenantialdoxime is obtained from the syn-isomeride

as already described, and also by the combination of its constituents; it crystallises in groups of colourless, slender needles melting at 144°. The molecular weight was determined by Raoult's method. The antialdoxime combines with aniline to form a compound which is deposited in long, colourless plates melting at 45—46°, and gives a violet coloration with calcium hypochlorite. With orthotolyl cyanate, both the anti- and syn-aldoximes yield *carborthotoluidothiophensynaldoxime*, $\overset{C_4SH_3\cdot C\cdot H}{\underset{N\cdot O\cdot CO\cdot NH\cdot C_6H_4Me}{\|}}$, which is deposited from ether in small, yellow needles melting at 66° with decomposition; on treatment with soda, orthoditolylcarbamide, orthotoluidine, thiophensynaldoxime, and thiophenic acid are formed.

It thus appears that the benzene antialdoximes, in their behaviour towards tolyl cyanate, differ from those of furfuraldehyde and thiophenaldehyde.

Œnanthaldoxime.—Methylœnanthaldoxime, $C_6H_{13}\cdot CH<\overset{NMe}{\underset{O}{|}}$, is prepared by the action of methyl iodide on the oxime, and is a viscid, yellow liquid readily soluble in ether, alcohol, or benzene, but more sparingly in water. On boiling with dilute sulphuric acid, œnanthaldehyde and β-methylhydroxylamine are formed, whilst, on heating with hydriodic acid, methylamine is obtained.

Benzylœnanthaldoxime, $C_6H_{13}\cdot CH<\overset{N\cdot CH_2Ph}{\underset{O}{|}}$, is prepared in a similar manner to the preceding compound, which it resembles in its reactions; it crystallises from benzene in colourless, lustrous plates melting at 83°. Œnanthaldoxime combines with phenyl cyanate to form a viscid, unstable compound.

By the action of œnanthaldehyde on hydroxylamine hydrochloride in alkaline solution, a yellow, viscid liquid is obtained which is probably the *antialdoxime;* it is soluble in ether, and does not crystallise even in presence of the synaldoxime, but on treatment with hydrogen chloride in ethereal solution and subsequent evaporation of the latter, the synaldoxime is deposited in crystals.

The cyanates employed by the authors were made by heating the corresponding urethane (in portions of 15 grams) with 2 parts of phosphoric anhydride; the distillate is fractionated once, and is then pure. The yield is 52—53 per cent. of the theoretical in the case of phenyl cyanate, and 67·3 per cent. in that of orthotolyl cyanate.

J. B. T.

Dipropargyl and Benzene. By J. W. Brühl (*Ber.*, **25**, 2638—2646).—Up to the present, the molecular heat of combustion of dipropargyl (854—883 Cal.) has not been accurately determined, but is certainly much greater than that of benzene (784—788 Cal.); this is in harmony with the chemical behaviour of the two substances which indicates that the intramolecular tension is greater in dipropargyl than in benzene. The author has already conjectured (Abstr., 1891, 630) that the differences between the molecular refractions and dispersions of these two hydrocarbons are in the opposite sense to the

differences between the heats of combustion; this is now shown to be the case. The dipropargyl employed was purified by distillation in a slow current of air in a vacuum at the ordinary temperature; a very slight resinous residue was left, and the hydrocarbon was obtained as a colourless liquid which turned yellow in a few hours. The molecular refraction of dipropargyl (25·74 for sodium light) is considerably less than that of benzene (26·13), and agrees remarkably well with the calculated value considering the great difficulty of preserving the hydrocarbon unchanged during the measurement. The presence of two acetylenic bonds in dipropargyl is thus clearly indicated, and the spectrometrical data are in complete accord with the chemical behaviour of the substance. W. J. P.

Action of Chlorine on Orthonitrotoluene in presence of Sulphur. By C. Haeussermann and C. Beck (*Ber.*, **25**, 2445—2446). —When orthonitrotoluene is added to half its weight of sulphur, heated to 130—140°, and chlorine passed in until the evolution of hydrogen chloride ceases, the fatty, and not the aromatic, part of the hydrocarbon is attacked, 30 per cent. of the latter being converted into orthonitrobenzyl chloride. C. F. B.

Derivatives of Metaxylene. By C. Ahrens (*Annalen*, **271**, 15—20).—*Diacetylnitroxylidine* [$Me_2 : NAc_2 : NO_2 = 1 : 3 : 4 : 6$] is obtained when nitroxylidine (m. p. 123°) is boiled for an hour with excess of acetic anhydride; it crystallises in colourless, well-defined plates, melts at 115°, and, on boiling with dilute alcohol, is converted into the monacetyl derivative (m. p. 161°) described by Grevingk (Abstr., 1885, 144).

Nitrometaxylenediazopiperidide, $NO_2 \cdot C_6H_2Me_2 \cdot N_2 \cdot C_5NH_{10}$, crystallises from alcohol in golden needles, melts at 51—52°, and is decomposed by concentrated halogen acids yielding the corresponding halogen derivatives of nitrometaxylene.

Fluoronitrometaxylene, $C_6H_2Me_2F \cdot NO_2$, is a volatile oil; the corresponding *chloro*-derivative, $C_6H_2Me_2Cl \cdot NO_2$, crystallises in needles, melts at 42°, and is soluble in alcohol; the *bromo*-derivative, $C_6H_2Me_2Br \cdot NO_2$, is volatile with steam, and forms long needles which melt at 57°; the *iodo*-derivative, $C_6H_2Me_2I \cdot NO_2$, is a brownish-yellow, crystalline compound melting at 86°.

Cyanonitrometaxylene, $NO_2 \cdot C_6H_2Me_2 \cdot CN$, crystallises from alcohol in long needles, and melts at 108—109°.

Nitrometaxylylic acid, $NO_2 \cdot C_6H_2Me_2 \cdot COOH$, prepared by heating the cyanide with concentrated hydrochloric acid at 150°, crystallises from hot alcohol in long, lustrous needles, melts at 196—197°, and is only sparingly soluble in boiling water, but readily in hot alcohol; it is probably identical with the acid obtained by Schaper (*Zeit. f. Chem.*, 1867, 13) by the oxidation of nitropseudocumene. The *amide*, $NO_2 \cdot C_6H_2Me_2 \cdot CO \cdot NH_2$, is a crystalline compound melting at 183°. The *ethyl* salt, $NO_2 \cdot C_6H_2Me_2 \cdot COOEt$, crystallises from dilute alcohol in needles, and melts at 75—76°. F. S. K.

Bivalent Carbon. By J. U. Nef (*Annalen*, **270**, 267—335).—Although carbonic oxide is an unsaturated compound, it is, relatively, very inert; it does not combine with iodine, or with halogen acids at 200°; it absorbs chlorine only very slowly in diffused light, and even in direct sunlight it is only very slowly and incompletely acted on by bromine. If, in the place of the oxygen atom in carbonic oxide, some less negative group were introduced, a substance would be obtained which would doubtless possess greater chemical activity than carbonic oxide; such substances are, possibly, hydrogen cyanide and its salts, and the isocyanides or carbylamines.

Starting from this assumption, the author has studied the properties of some isocyanides; he claims to have proved that they contain bivalent carbon, and are represented by the general formula R·N:C; he is also of opinion that the constitution of hydrogen cyanide is very probably expressed by the formula H·N:C. The following are the grounds on which the existence of a bivalent carbon atom in the isocyanides is assumed:—The isocyanides combine with halogens and with halogen acids, even at −15°, with development of great heat, yielding products of the constitution $R·N:CX_2$ and $(R·N:CHX)_2,HX$ respectively. They are readily converted into thiocarbimides by sulphur at 130°, and into thiamides by hydrogen sulphide at 100°. They combine with carbonyl chloride at −15° yielding compounds of the general formula R·N:CCl·CO·CCl:N·R, and with acetic chloride at 100° they form imidochlorides of pyruvic acid of the general formula R·N:CClAc. They combine with primary amines at 180—220°, yielding formamidine derivatives of the constitution R·N:CH·NHR′. Orthotolyl isocyanide combines directly with benzoic chloride at 100° yielding the compound described below.

Phenyl isocyanide, PhN:C, prepared by treating aniline with chloroform and alcoholic potash, freed from aniline and diphenylformamidine by shaking its ethereal solution with dilute hydrochloric acid, and purified by distillation, is a colourless oil, which soon turns greenish-yellow on keeping. It boils at 64° under a pressure of 20 mm., at 71° under a pressure of 30 mm., and at 78° under a pressure of 40 mm., leaving a small quantity of a blue residue; the distillate is colourless, but soon turns blue, and then gradually darkens; after some time, deep purple-red needles are deposited, and, on long keeping, the whole is converted into a solid resin, which is probably a polymeride. Phenyl isocyanide is reduced by sodium and boiling amyl alcohol, being reconverted into methylaniline; when treated with glacial acetic acid at the ordinary temperature, it yields formanilide and acetic anhydride, together with considerable quantities of acetanilide. It reacts violently with anhydrous formic acid, even at 0°, yielding formanilide and carbonic oxide, the latter being probably generated by the decomposition of the formic anhydride which is doubtless produced as an intermediate product; with anhydrous oxalic acid at 0°, it yields formanilide, carbonic oxide, and carbonic anhydride, a reaction which seems to show that oxalic anhydride is also incapable of existence. When heated at 130° with an alcoholic solution of sodium ethoxide, it yields a large quantity of diphenylformamidine; it reacts with silver oxide and with mercuric oxide

with explosive violence, but, when diluted with ether and then warmed with mercuric oxide at 40—50°, it gives traces of phenyl cyanate, the oxide being reduced to metal.

Isocyanophenyl dichloride (*phenylimidocarbonyl chloride*), $NPh{:}CCl_2$, is formed when chlorine is passed into a well-cooled chloroform solution of phenyl isocyanide until the colour of the solution suddenly changes from blue to yellow. It is a colourless oil, boils at 209—210° (thermometer entirely in vapour), and has a very irritating action on the eyes. When heated with glacial acetic acid, it yields acetaniilide; with water, symmetrical diphenylcarbamide; with silver oxide, phenyl cyanate; with alcohol, phenylurethane; with aniline, α-triphenylguanidine hydrochloride. The isocyanophenyl dichloride, previously described by Sell and Zierold (*Ber.*, **7**, 1228), is a mixture of the compound described above with a chloro-derivative, $C_6H_4Cl{\cdot}N{:}CCl_2$.

Phenyl isocyanide combines with bromine (1 mol.) in cold chloroform solution, yielding a yellow, unstable oil, which cannot be distilled, but which has, doubtless, the constitution $NPh{:}CBr_2$; it also combines with iodine (1 mol.) in carbon bisulphide solution to form an oily product.

Mesoxanilide imidochloride (*phenylamidomesoxalic chloride*),

$$NPh{:}CCl{\cdot}CO{\cdot}CCl{:}NPh,$$

can be obtained by treating phenyl isocyanide with carbonyl chloride at −20°, and then allowing the temperature of the mixture to rise slowly; it is a thick, yellow, hygroscopic oil, boils at 145—152° under a pressure of 15—20 mm., with slight decomposition, and is decomposed by cold 10 per cent. soda, yielding a considerable quantity of phenyl isocyanide.

Mesoxanilide alcoholate, $NPh{:}C(OH){\cdot}C(OH)(OEt){\cdot}C(OH){:}NPh$, is formed when the imidochloride is treated with water, and the solid hydrate obtained in this way recrystallised from boiling alcohol. It forms long, moss-like, colourless needles, begins to turn yellow at 100°, and melts at 145—151° with decomposition; it is readily soluble in dilute soda and in hot alcohol, but only very sparingly in cold alcohol and boiling water; it undergoes dissociation in boiling alcoholic or boiling benzene solution, combination taking place again on cooling. It combines with phenylhydrazine, forming a colourless substance of the constitution

$$NPh{:}C(OH){\cdot}C(N_2H_2Ph)(OEt){\cdot}C(OH){:}NPh;$$

this compound loses alcohol at 115°, being converted into mesoxanilidephenylhydrazone (see later).

Mesoxanilide, $NPh{:}C(OH){\cdot}CO{\cdot}C(OH){:}NPh$, prepared by heating the alcoholate or hydrate at 108—116° for about 16 hours, is a yellow powder, and combines readily with water and with alcohol to form the colourless hydrate and alcoholate respectively; it sinters at 163°, melts at 190°, and can be sublimed in small quantities. It combines with phenylhydrazine in dry benzene solution, yielding a compound of the constitution $NPh{:}C(OH){\cdot}C(N_2H_2Ph)(OH){\cdot}C(OH){:}NPh$, which, when heated at 100°, is converted into mesoxanilidephenylhydrazone.

Mesoxanilidephenylhydrazone, $NPh{:}C(OH){\cdot}C(N_2HPh){\cdot}C(OH){:}NPh$,

crystallises from glacial acetic acid in yellow plates, melts at 163° with decomposition, and is moderately easily soluble in glacial acetic acid, acetone, and benzene, but only sparingly in alcohol and ether, and insoluble in alkalis; it does not combine with water or with alcohol.

Mesoxanilide hydrate, $NPh{:}C(OH)\cdot C(OH)_2\cdot C(OH){:}NPh$, separates from boiling water, in which it is only very sparingly soluble, in colourless needles, and behaves like the corresponding alcoholate when heated in a capillary tube; it is soluble in benzene and ethyl acetate, and also in warm dilute soda and sodium carbonate, from which it is precipitated unchanged by acids. It is a strong acid, and turns blue litmus red; when boiled with soda, it is decomposed into aniline and mesoxalic acid.

When ethyl oxanilate is hydrolysed with alcoholic potash, it yields an oxanilic acid melting at 210°, which is probably a polymeride of the known oxanilic acid; on treatment with phosphorus pentachloride, this supposed polymeride is converted into oxanilic chloride (m. p. 82·5°), which, when decomposed with water, yields the known oxanilic acid (m. p. 149°).

Pyruvic anilide imidochloride (*phenylimidopyruvic chloride*), $NPh{:}CClAc$, can be obtained by slowly and carefully heating a mixture of pure phenyl isocyanide and acetic chloride to about 100° on a water-bath; the product is freed from polymerides by dissolving it in ether. It is a yellow, hygroscopic oil, boils at 136° under a pressure of 30 mm., and is very unstable, gradually decomposing into acetic chloride and polymeric phenyl isocyanide, on keeping; when treated with alcohol, it is converted into diphenylformamidine hydrochloride, and, when poured into dilute acid, it is decomposed into hydrogen chloride, acetic acid, and phenyl isocyanide.

Pyruvic anilide, $NPh{:}CAc\cdot OH$, is produced when the preceding compound is treated with water; it crystallises in long, colourless needles, melts at 104°, and is readily soluble in hot alcohol and chloroform, but only moderately easily in ether, and almost insoluble in cold water; it is only slowly acted on by boiling dilute hydrochloric acid and dilute sulphuric acid, but is immediately decomposed by cold dilute soda, being converted into a colourless, flocculent substance which melts at 196°, and is probably a polymeride. When treated with phenylhydrazine in cold ethereal solution, it yields a colourless additive compound of the constitution

$$NPh{:}C(OH)\cdot CMe(OH)\cdot N_2H_2Ph;$$

this melts at 101—105° with liberation of water, and, when warmed with soda, it is decomposed into aniline and pyruvic acid. The *hydrazone*, $NPh{:}C(OH)\cdot CMe{:}N_2HPh$, prepared by heating the additive product at 78°, or by boiling it with alcohol or glacial acetic acid, crystallises in colourless needles, melts at 176°, and dissolves freely in hot benzene, alcohol, and glacial acetic acid, but is insoluble in alkalis and dilute acids.

Phenylimidoformic chloride hydrochloride, $2NPh{:}CHCl,HCl$, can be obtained by shaking an ethereal solution of phenyl isocyanide, cooled to −15°, with anhydrous hydrogen chloride. It is a colourless, very hygroscopic, unstable powder, and is decomposed by water and

alcohol with considerable development of heat; it is soluble in chloroform, but insoluble in ether and light petroleum. When treated with cold soda, or with water, it yields formanilide, diphenylformamidine, aniline, and formic acid.

The compound formed by the combination of anhydrous hydrogen cyanide with anhydrous hydrogen iodide, and described by Gautier (*Bull. Soc. Chim.* [4], **17**, 143), is very unstable, and could not be analysed; attempts to prepare imidoformic chloride and phenylimidoformic chloride were unsuccessful.

Orthotolyl isocyanide, $C_6H_4Me{\cdot}N{:}C$, prepared from orthotoluidine, as described in the case of the corresponding phenyl derivative, is a colourless oil, boils at 75° under a pressure of 16 mm., at 101° under a pressure of 55 mm., and at 183—184° with slight decomposition under a pressure of 753 mm.; it is much more stable than phenyl isocyanide, and does not readily undergo polymerisation, but when heated at 235—245° for three hours it is completely converted into orthotolyl cyanide. It is decomposed by formic acid, yielding carbonic oxide and formorthotoluidide, and with acetic acid it gives acetic anhydride, formorthotoluidide, and acetorthotoluidide; its behaviour with oxalic acid is similar to that of phenyl isocyanide, and, when heated with benzoic acid, it yields benzoylorthotoluidide as principal product. It is decomposed by orthotoluidine at 190—220° with formation of di-orthotolylformamidine (m. p. 151°); when heated with aniline at 190—220°, it yields a mixture of products, from which diphenylformamidine alone could be isolated. It combines with carbon bisulphide at 130°, yielding orthotolylthiocarbimide; when heated with an alcoholic solution of hydrogen sulphide at 100°, it gives thioformorthotoluidine (m. p. 100—101°).

Isocyanorthotolyl dichloride (tolylimidocarbonyl chloride),

$$C_6H_4Me{\cdot}N{:}CCl_2,$$

is formed when dry chlorine is passed into a well-cooled chloroform solution of orthotolyl isocyanide; it is a colourless oil, and boils at 214—215° (compare Lachmann, *Ber.*, **12**, 1349); when treated with orthotoluidine, it is converted into tri-orthotolylguanidine hydrochloride.

Mesoxatoluidide hydrate,

$$C_6H_4Me{\cdot}N{:}C(OH){\cdot}C(OH)_2{\cdot}C(OH){:}N{\cdot}C_6H_4Me,$$

can be obtained by treating orthotolyl isocyanide with carbonyl chloride in the cold, and decomposing the product with water; it crystallises from hot water, in which it is only very sparingly soluble, in colourless needles, turns yellow at 100°, and melts at 127—131° with decomposition. It turns blue litmus red, is soluble in dilute sodium carbonate, and is decomposed into its constituents by boiling anhydrous benzene, combination taking place again, to a certain extent, on cooling the solution.

Pyruvic orthotoluidide, $C_6H_4Me{\cdot}N{:}CAc{\cdot}OH$, seems to be produced, together with formorthotoluidide, when orthotolyl isocyanide is warmed with acetic chloride for five minutes on the water-bath, and the unstable imidochloride obtained in this way slowly poured into a

large volume of water; the aqueous solution is extracted with ether, the extract shaken with soda, the alkaline liquid acidified, extracted with ether, and the ethereal solution evaporated. The compound obtained in this way crystallises in hexagonal plates, melts at 62°, and is very readily soluble in water; it is probably a *hydrate* of the constitution $C_6H_4Me{\cdot}N{:}C(OH){\cdot}CMe(OH)_2$, as, when treated with calcium chloride in ethereal solution, it is transformed into a crystalline compound, melting at 177°, which is probably a polymeride; the latter is insoluble in ether and water, but readily soluble in hot alcohol and in dilute soda, from which it is reprecipitated by acids.

Benzoylformorthotoluidide, $C_6H_4Me{\cdot}N{:}CBz{\cdot}OH$, prepared by heating orthotolyl isocyanide with benzoic chloride on the water-bath, and decomposing the product with water, crystallises from ether in colourless needles, melts at 108°, and is readily soluble in hot ether and alcohol, but almost insoluble in boiling water. It dissolves in warm soda, being reprecipitated on acidifying the solution, but, when boiled with excess of potash, it is decomposed with formation of orthotoluidine; it is very stable towards concentrated hydrochloric acid and sulphuric acid. When its warm solution is treated with phenylhydrazine and then cooled, the colourless *hydrate* of the hydrazone is precipitated; this compound has doubtless the constitution

$$C_6H_4Me{:}C(OH){\cdot}CPh(OH){\cdot}N_2H_2Ph,$$

and when its solutions are heated it is quickly converted into a yellow *hydrazone;* it is not decomposed by cold soda, but when warmed with sodium ethoxide in alcoholic solution it is converted into the hydrazone of benzoylformic acid.

Paratolyl isocyanide, $C_6H_4Me{\cdot}N{:}C$, is a colourless oil, boiling at 99° with slight decomposition under a pressure of 36 mm.; it undergoes change only slowly on keeping.

Isocyanoparatolyl dichloride, $C_6H_4Me{\cdot}N{:}CCl_2$, is a colourless oil with an irritating odour, and boils at 225—226° (uncorr.); when treated with paratoluidine, it is converted into triparatolylguanidine hydrochloride.

The above experiments having shown that phenylhydrazine combines with certain compounds containing a carbonyl group to form additive products, which are converted into hydrazones by the loss of 1 mol. H_2O, the author, arguing from analogy, assumes that when hydroxylamine combines with ketones, additive compounds are first formed; he supposes that in the production of benzilediоxime, for example, there is formed an intermediate product of the constitution $OH{\cdot}NH{\cdot}CPh(OH){\cdot}CPh(OH){\cdot}NH{\cdot}OH$, which, by loss of 2 mols. H_2O, is converted into the dioxime; this last stage of the reaction can take place in three different ways, yielding, in each case, a dioxime which is chemically isomeric with the other two. Since it may be assumed that similar intermediate products are formed in other cases, it is quite possible that the supposed stereochemical isomerism of the oximes is, in reality, a matter of true chemical isomerism, especially as, in the author's opinion, not a single fact to the contrary has yet been established.

The rest of the paper consists of a discussion of the constitution of

hydrogen cyanide and of short replies to v. Pechmann (this vol., p. 431) and to Brühl (this vol., p. 583). F. S. K.

Homocatechol and two Nitrohomocatechols. By H. Cousin (*Compt. rend.*, **115**, 234—236).—The product of the action of hydrogen iodide on creosol at 180° is fractionated, and the portion boiling between 230° and 265° is repeatedly treated with boiling water, the solution being filtered after cooling and evaporated on a water-bath. The syrupy liquid thus obtained is distilled under reduced pressure. The greater part boils at 210—215° under a pressure of 190 mm., and forms a colourless, viscous liquid, which solidifies to a crystalline mass melting at 49—50°. It contains a small quantity of catechol.

Homocatechol (11 grams) is dissolved in ether (500 c.c.), mixed gradually with fuming nitric acid (4 c.c.), and, after 24 hours, agitated with a small quantity of water. The ethereal layer is distilled, and the residue is mixed with water and again distilled. The condensed water is yellow, and contains oily drops; it is heated until these drops dissolve, and then allowed to cool, when *nitrohomocatechol*, $C_7H_7NO_4$, separates in golden-yellow lamellæ, which melt at 79—80°, begin to decompose at about 180°, are coloured deep red by alkalis, and dissolve slightly in cold water, but are more soluble in hot water, alcohol, and ether.

Homocatechol (5 grams) is dissolved in water (150 c.c.), mixed with a solution of sodium nitrite (18·5 grams), and dilute hydrochloric acid added gradually until there is an abundant evolution of nitrogen oxides. The deep-red mixture is extracted with ether, which is separated and distilled, and the brown, crystalline residue is dried over sulphuric acid; it is then crystallised from boiling benzene and finally from dilute alcohol. This compound is a *nitrohomocatechol*, $C_7H_7NO_4$, but is isomeric with the preceding compound. It forms small, sulphur-yellow needles, only slightly soluble in cold water, but soluble in hot water, alcohol, ether, or benzene; it melts at about 180° with incipient decomposition. When treated with excess of alkali, it gives a beautiful, purple coloration. If, however, potassium hydroxide or ammonia is added to a hot solution until the purple coloration just begins to be produced, the liquid, when cooled, deposits orange-yellow needles of the monobasic alkali salts, which are easily purified by recrystallisation from water. The *potassium* salt has the composition $C_7H_6KNO_4 + H_2O$. C. H. B.

Condensation of Unsaturated Hydrocarbons with Phenols. By W. Koenigs and C. Mai (*Ber.*, **25**, 2649—2658).—One of the authors has already described the condensation of monatomic phenols with unsaturated hydrocarbons (Abstr., 1891, 571, and this vol., p. 446). The present paper deals with the behaviour of polyatomic phenols. Quinol, resorcinol, and catechol unite with 2 mols. of the unsaturated hydrocarbons, and well-crystallised diamyl derivatives were obtained. Pyrogallol yields a diamyl derivative, but a triamyl derivative could not be obtained.

Diamylquinol, $C_6H_2(C_5H_{11})_2(OH)_2$, is obtained by adding sulphuric acid (50 c.c.), with cooling, to a solution of quinol (25 grams) in

acetic acid (250 grams), and then gradually adding isoamylene (50 grams, 2·5 mols.) to the cold mixture. After 24 hours, the crystalline product is collected, washed with acetic acid, dissolved in ether, and the ethereal solution shaken with soda, dried over potash, evaporated to dryness, and the crystalline mass thus obtained is recrystallised from benzene. It forms colourless, compact, tetragonal pyramids, melts at 185°, is easily soluble in alcohol, ether, and chloroform, less so in cold benzene and acetic acid, very sparingly in light petroleum, almost insoluble in water, and in soda, ammonia, and the fixed alkalis. The concentrated alcoholic solution turns yellowish-red on the addition of potassium or sodium hydroxide, but, on adding water, unaltered diamylquinol is precipitated. When warmed in alkaline alcoholic solution, it yields diamylquinone. Phenylhydrazine and hydroxylamine are without action on diamylquinol. Ferric chloride, ordinary and fuming nitric acid, and bromine in carbon bisulphide all convert it into the corresponding quinone. When warmed with concentrated sulphuric acid, it is decomposed. It cannot be sublimed without decomposition, is not volatile with steam, and is very stable towards light and air.

Diacetyldiamylquinol, $C_6H_2(C_5H_{11})_2(OAc)_2$, is obtained by boiling the preceding compound with acetic anhydride. It crystallises from alcohol in beautiful, four-sided tablets, melts at 116°, is easily soluble in the ordinary organic solvents, and insoluble in water. When boiled with dilute alcoholic sulphuric acid, it yields diamylquinol; with alcoholic potash, it yields diamylquinone.

Diamylquinol phenylcarbamate, $(NHPh\cdot COO)_2C_6H_2(C_5H_{11})_2$, is obtained by warming diamylquinol with phenyl isocyanate. It is insoluble in most solvents, dissolves sparingly in acetone and acetic acid, separates as a crystalline powder, and melts at 248°.

Quinol diisoamyl ether, $C_6H_4(OC_5H_{11})_2$, is obtained by gradually adding a solution of potassium hydroxide (3·1 grams) in alcohol (15 c.c.) to a warm mixture of quinol (3 grams) and isoamyl iodide (11 grams). It crystallises in silky, colourless needles, melts at 65°, is volatile with steam, and is very easily soluble in organic solvents, with the exception of cold alcohol, in which it is somewhat sparingly soluble.

Neither the diisoamyl ether nor the diacetate of quinol yields condensation products with amylene.

Diamylquinone, $C_6H_4O_2(C_5H_{11})_2$, is obtained by boiling a mixture of diamylquinol (5 grams), alcohol (50 grams), and dry ferric chloride (15 grams) in a reflux apparatus for one hour. It crystallises from alcohol in long, bright yellow needles, melts at 140°, sublimes in beautiful, slender, pale yellow needles, is easily volatile with steam, and is easily soluble in ether, benzene, chloroform, and acetone, somewhat sparingly so in cold alcohol and acetic acid, sparingly in light petroleum, and almost insoluble in water. It is not altered by treatment with sulphurous acid, but when boiled with zinc-dust and acetic acid, it is reconverted into diamylquinol. It is not attacked by alkalis, calcium chloride, aniline, phenylhydrazine, hydrogen bromide, hydroxylamine, acetic anhydride, or phenyl isocyanate.

Diamylresorcinol, $C_6H_2(C_5H_{11})_2(OH)_2$, is obtained in a similar way to diamylquinol. It crystallises from light petroleum in slender,

colourless needles, melts at 89°, is extremely soluble in all organic solvents, and is insoluble in water, soda, and ammonia. It dissolves easily in potassium, sodium, and barium hydroxides, and is precipitated from the solution unchanged by the addition of acids. It is easily volatile with steam. When boiled in alcoholic solution with methyl iodide and potassium hydroxide, it yields a dimethyl ether which melts at 64°. The *diacetyl derivative* melts at 89°.

Diamylcatechol is obtained by allowing a mixture of catechol, acetic acid, sulphuric acid, and amylene to remain five days. The oily product is freed from polyamylenes by distillation in a vacuum at 100°, and the residue distilled with steam, dried on porous plates in a vacuum, and crystallised from light petroleum. It crystallises in aggregates of colourless needles, melts at 60°, is very easily soluble in organic solvents, and insoluble in alkalis. When the alcoholic solution is treated with a few drops of concentrated potassium hydroxide solution, it assumes a beautiful, blue colour, which changes to dirty green on the addition of water, and an oil is precipitated, which turns to a dark-green resin when warmed. With ferric chloride, the alcoholic solution gives a green coloration, and, with lead acetate, a white, gelatinous precipitate, which quickly turns green when dried. The authors were unable to determine if diamylcatechol contains two hydroxyl groups, owing to lack of material.

Diamylpyrogallol, $C_6H(C_5H_{11})_2(OH)_3$, is obtained when a mixture of pyrogallol, amylene, acetic acid, and sulphuric acid is left for 5 to 6 days. It crystallises from light petroleum in long, colourless needles which turn red on exposure to air, melts at 90°, is not volatile with steam, is very easily soluble in organic solvents, insoluble in water, sodium carbonate, and ammonia, and dissolves easily in sodium and potassium hydroxides, yielding a solution which at once turns violet. With ferric chloride, the alcoholic solution gives first a green and then an intense violet coloration. The *triacetate* crystallises from alcohol in colourless, lustrous needles, and melts at 145°.

The authors also describe experiments with tetrahydronaphthylphenol and metacresolphenylethane.

Tetrahydronaphthylphenol, $C_{10}H_{11}\cdot C_6H_4\cdot OH$, is obtained by the condensation of dihydronaphthalene with phenol. When mixed with pumice and heated to dull redness in a current of carbonic anhydride, it is partially resolved into naphthalene and phenol, and the remainder distils unchanged. Naphthylphenol cannot be obtained from it by distillation with zinc-dust or with lead oxide.

Tetrahydronaphthylanisoïl, $C_{10}H_{11}\cdot C_6H_4\cdot OMe$, is obtained by boiling tetrahydronaphthylphenol with potash, methyl alcohol, and methyl iodide for four hours in a reflux apparatus. It crystallises from alcohol in beautiful, long, silky needles, melts at 71°, and is very easily soluble in ether, chloroform, benzene, and carbon bisulphide, more sparingly in cold alcohol, and almost insoluble in water. When treated with excess of bromine, it yields a mixture of di- and tri-brominated derivatives. The authors were unable to obtain naphthylanisoïl from it.

Kraemer and Spilker (Abstr., 1891, 206) have stated that the hydrocarbons obtained by the condensation of cinnamene with homo-

logues of benzene, by means of sulphuric acid, are converted into anthracene derivatives when heated at a dull red heat. The authors have examined the behaviour of metacresolphenylethane, and find that, when heated with zinc-dust, it is decomposed with formation of metacresol. When heated alone, a fluorescent compound was obtained, which dissolves in alkali with a yellow coloration, and is, perhaps, hydroxyanthracene; but the yield was so small that satisfactory results could not be obtained.

The bye-products formed in the preparation of metacresolphenylethane were found to contain unaltered cresol, and the liquid dicinnamene, $C_{16}H_{16}$, which boils at 310°. The latter is also obtained in large quantities by allowing a solution of cinnamene in pure sulphuric acid (1 vol.) and acetic acid (9 vols.) to remain for a time.

E. C. R.

Constitution of Pyrogallol. By De Forcrand (*Compt. rend.*, **115**, 284—286).—The heat of neutralisation of pyrogallol by dilute soda as measured by Berthelot and Werner, namely, +6·40, +6·38, and +1·02 Cal., for the three successive hydroxyls, seems to indicate that the third hydroxyl occupies the ortho-position relatively to the others, since the corresponding values for catechol are +6·26 and +1·40 Cal., whilst those for resorcinol are +8·22 and +7·36, and for quinol +8·00 and +6·36. The mean value for pyrogallol (4·60), moreover, is less than that for phloroglucol (+6·09), just as the mean value for catechol (+3·83) is less than that for its isomerides (+7·79). In drawing conclusions, however, from successive values obtained with dilute solutions, it is necessary to be cautious on account of the very considerable influence of the heat of dissolution. Catechol, for instance, which is apparently the weakest of the three dihydroxybenzenes, is found to be the strongest when the heat of dissolution is taken into account (see this vol., p. 1184).

To clear up the matter, the authors have redetermined the heat of neutralisation of the successive hydroxyls of pyrogallol, calculated for the solid state. The total amount is +116·09 Cal., giving a mean value of +38·70 for each hydroxyl. The successive values are approximately +41·34, +39·09, and +35·66 Cal. On comparing the mean value with those for resorcinol, +38·60, catechol, +39·02, and quinol, +37·36, it would seem that the constitution 1 : 3 : 5, analogous to that of resorcinol, is the more probable, were it not that the properly calculated successive values (+38·70 and +38·50 for resorcinol), which have a far greater indicative power than the mean values, show the essential constitutional difference between the two substances, namely, the ability of pyrogallol and the inability of resorcinol to form intermediate molecular combinations in the course of neutralisation. The asymmetrical constitution, necessitating the para-position for the extreme hydroxyls, is seen to be impossible when the mean value for those groups (+38·50) is compared with those for quinol, and for the single hydroxyl of phenol (+39·10), and this value, moreover, is so near that for resorcinol as to point with certainty to the meta-position for the extreme groups. The third group, notwithstanding its ortho-position relatively to the others, bears practically the same value as the single hydroxyl of

phenol, probably because it has to be dislodged from a molecular combination before it can be neutralised, and thus acts as if it were independent of them. JN. W.

Aromatic Sugars. By E. FISCHER and A. J. STEWART (*Ber.*, **25**, 2555—2563).—*Phenyldibromhydroxybutyronitrile*,

$$CHPhPr{\cdot}CHBr{\cdot}CH(OH){\cdot}CN,$$

is prepared by dissolving cinnamaldehydecyanhydrin (100 grams) in chloroform (500 grams), and adding bromine (100 grams); the nitrile is precipitated on the addition of light petroleum, and crystallises from chloroform, dilute alcohol, or light petroleum, in small, colourless needles which darken at 130°, and melt at 140° with evolution of gas. The yield is quantitative.

On heating the nitrile with 20 parts of hydrochloric acid (20 per cent.) for two hours in a reflux apparatus, *phenylbromodihydroxybutyrolactone*, $CHPh<\begin{matrix}CHBr\\O\cdot CO\end{matrix}>CH{\cdot}OH$, is formed, and crystallises from water in colourless needles which melt at 137° (uncorr.) without decomposition; it is sparingly soluble in ether, chloroform, and light petroleum, but readily so in alcohol. The aqueous solution is neutral. The yield is 15 per cent. of the theoretical.

Phenyltrihydroxybutyric acid is obtained by the action of barium hydroxide on the bromolactone in molecular proportion; after the removal of the barium and hydrobromic acid, and evaporation of the aqueous solution, the *lactone* is deposited in slender, colourless needles which melt at 115—117°. The *silver salt* of the acid crystallises from water in lustrous prisms or plates; the *sodium salt* is crystalline and soluble in alcohol. The *phenylhydrazone* is deposited from water in small, colourless prisms or plates which melt at 167°, with previous softening at 160°, and give a rose coloration on the addition of sulphuric acid and ferric chloride.

Phenyltetrose, $OH{\cdot}CHPh{\cdot}CH(OH){\cdot}CH(OH){\cdot}COH$, is prepared by the reduction of the lactone (5 grams) with 2·5 per cent. sodium amalgam (100 grams) in dilute alcoholic solution; the liquid is well cooled, and maintained acid by the frequent addition of sulphuric acid; the operation lasts ¾ hour; the solution is separated from the mercury, treated with soda in order to remove any unaltered lactone, neutralised with sulphuric acid, and evaporated to dryness in a vacuum; the residue is extracted with absolute alcohol, the solution treated with ether, and again evaporated to dryness; this residue is now extracted with ether, and after the removal of the latter, the tetrose remains as a colourless syrup which is readily soluble in water, alcohol, and ether, and reduces alkaline copper solutions on boiling. The *phenylhydrazone* crystallises from water in small, slender, lustrous plates, melting at 154°; it is sparingly soluble in ether and benzene, but more readily in alcohol. With concentrated sulphuric acid, a brown coloration is produced; with concentrated hydrochloric acid, the tetrose is regenerated.

On treating phenylhydroxycrotonic acid with bromine in chloroform solution, *phenylbromhydroxycrotonic acid*, $C_{10}H_9BrO_3$, is formed,

and is deposited from ether, on the addition of light petroleum, in colourless crystals, melting at 95—100°; the yield is 90 per cent. of the theoretical. By the action of soda at ordinary temperatures on the preceding compound, a *phenylketohydroxybutyric acid*, $CH_2Ph{\cdot}CO{\cdot}CH(OH){\cdot}COOH$ or $CH_2Bz{\cdot}CH(OH){\cdot}COOH$, is formed, which crystallises from water, or from ether on the addition of light petroleum, and melts at 118° (uncorr.). This acid reduces alkaline copper and silver solutions at the ordinary temperature, and becomes yellow on heating with alkalis. With phenylhydrazine, a yellow, amorphous, insoluble compound is formed. The *oxime* is deposited from water in hard, colourless, well developed crystals, which melt at 125° (uncorr.).

Phenylisodihydroxybutyric acid is prepared by the reduction of the ketonic acid with sodium amalgam; it is a colourless, viscid liquid, isomeric with Biedermann's phenyldihydroxybutyric acid. The *silver salt* is colourless and crystalline; the *phenylhydrazone* crystallises from water in small, colourless needles which melt at 161—162°. The yield is 30 per cent. of the acid employed. J. B. T.

Mercurioanilido-compounds. By L. Pesci (*Gazzetta*, **22**, 373—384).—A molecular compound of mercuriophenylamine and aniline is prepared by slowly adding 6 per cent. mercuric chloride solution (50 c.c.) to a mixture of a saturated aqueous solution (500 grams) of aniline, 30 per cent. aqueous soda (20 c.c.), and sufficient water to render the liquid clear. More soda (60 c.c.) and mercuric chloride (150 c.c.) are then cautiously added, and the white precipitate which separates collected, and washed with dilute aniline solution until the filtrate no longer contains chlorine. The product after drying over sulphuric acid has the composition $4NHgPh,5NH_2Ph$, and consists of microscopic, transparent octahedra, which have a caustic taste and a strongly alkaline reaction; when crystallised from water containing aniline (2 per cent.) and caustic potash (1 per cent.) at 80°, beautiful four-sided tables are obtained of the composition $6NPhHg,7NH_2Ph$; on crystallisation from potash (15 per cent.), however, it is deposited in splendid hexagonal tables, having the composition $NPhHg,NH_2Ph$. These three compounds are similar in properties, and are converted into a brown substance by the ordinary solvents. *Mercuriophenylamine*, NPhHg, is prepared by the action of dilute alkalis on the acetate suspended in water; it separates in colourless laminæ of a nacreous lustre. It has a strongly alkaline reaction and caustic taste, is sparingly soluble in water, insoluble in alcohol and ether, and on heating decomposes without melting. Its salts are obtained by the action of dilute acids on the preceding molecular compounds; they are decomposed by hydrogen sulphide with formation of mercuric sulphide. The *acetate*, $NPhHg,Ac{\cdot}OH$, forms brilliant, highly refractive, colourless crystals, which are very soluble in acetic acid, but insoluble in water, alcohol, and ether. The *nitrate* forms colourless, microscopic pyramids, which are soluble in potash and mineral acids, but insoluble in water. *Hydrogen mercuriophenylamine sulphate*, $NPhHg,H_2SO_4$, is obtained in colourless, microscopic needles, in-

soluble in water and alcohol, soluble in aqueous potash and mineral acids; it has an acid reaction, and decomposes at about 150° without melting. The *hydriodide* is obtained as a flocculent, yellow precipitate by the action of potassium iodide solution on the acetate; it is practically insoluble in water, alcohol, acids, and alkalis. The *hydrobromide* and hydrochloride (compare Förster, *Annalen*, **175**, 25) are amorphous, yellow powders, insoluble in water and mineral acids, and partially soluble in alkalis. The hydrochloride readily dissolves in a boiling alcoholic solution of aniline hydrochloride; on cooling, thin, colourless needles, having the composition $NPhHg,HCl,NH_2Ph,HCl$, separate. This substance has been prepared by Gerhardt (*Trait. de Chem. Org.*, iii, 86) and by H. Schiff (*Compt. rend.*, **56**); it decomposes at 150°, and its solution in boiling water, on cooling, deposits thin needles of a substance not yet studied.

W. J. P.

Additive Products of Hydrogen Iodide and Nitriles. By H. Biltz (*Ber.*, **25**, 2533—2545).—Benzonitrile combines very readily with concentrated hydriodic acid, forming a crystalline fairly stable additive product, having the composition $C_6H_5CN,2HI$, which may be preserved for months when anhydrous, but is decomposed by moisture. It forms lemon-yellow crystals, melts with decomposition at 135—140°, and on distillation splits up into its components, which partially reunite in the receiver. Most solvents also bring about the same change, but when heated with phenol, it yields ammonium iodide, a little phenyl benzoate, benzamide, and a colouring matter, which proved to be identical with benzaurine (Abstr., 1880, 239). The formation of the latter may be readily explained if the additive product is diiodobenzylamine, $C_6H_5{\cdot}CI_2{\cdot}NH_2$, the reaction taking place as follows:—

$$NH_2{\cdot}CPhI_2 + 2C_6H_5{\cdot}OH = OH{\cdot}C_6H_4{\cdot}CPh{<}\begin{matrix}C_6H_4\\ |\\ O\end{matrix} + NH_4I + HI.$$

The compound therefore corresponds with the chloride,

$$C_6H_5{\cdot}CCl_2{\cdot}NH_2,$$

obtained by Wallach from phosphorus pentachloride and benzamide, but, unlike the latter, it is not converted into benzamide by the action of water.

The formation of similar additive compounds with hydrogen iodide takes place with a large number of both aliphatic and aromatic nitriles; in the former series, the iodides of acetamide, propionamide, and succinamide have been prepared from the corresponding nitriles, and all resemble the benzonitrile derivative in their general properties, but in addition yield by the action of water, a certain quantity of the amide and corresponding acid. Ortho-, meta-, and para-tolunitrile, ortho-, meta-, and para-nitrobenzonitrile, benzyl cyanide, terephthalonitrile, α- and β-naphthonitrile, and cinnamonitrile all yield dihydriodo-derivatives, whilst triphenylacetonitrile and mandelic nitrile are not acted on by hydriodic acid. All the compounds have a yellow to brown or red colour, and melt with de-

composition between 100° and 140°; none of the aromatic compounds yield the amide or corresponding acid on treatment with water.

H. G. C.

Condensation Products with Formaldehyde. By G. Pulvermacher (*Ber.*, **25**, 2762—2765).—Continuing his former work (this vol., p. 579), the author has investigated the condensation products obtained by the action of formaldehyde on the three nitranilines.

Methylenedimetanitraniline, $CH_2(NH\cdot C_6H_4\cdot NO_2)_2$, was obtained by adding an excess of a 40 per cent. solution of formaldehyde to an almost boiling solution of metanitraniline. It crystallises in orange-yellow needles insoluble in water, ether, benzene, and chloroform, sparingly soluble in alcohol, and melts at 213°. It is strongly basic in character. The *picrate* forms yellow needles melting at 120°; the *aurochloride* easily soluble, light yellow rhombs; the *platinochloride* sparingly soluble golden-yellow rods. *Methylenediparanitraniline* crystallises in fine, lemon-yellow needles melting at 232°. It is insoluble in water and ether, very sparingly soluble in alcohol. It is much less basic in character than the meta-compound, and no definite salts were obtained. *Methylenediorthonitraniline* is much less readily formed than its two isomerides. It crystallises in yellow needles, is sparingly soluble in alcohol, soluble in ether, and insoluble in water, and melts at 195°. The *picrate* and *aurochloride* are crystalline, the *platinochloride* amorphous. Even long continued boiling with hydrochloric acid caused no decomposition of the ortho-compound, whilst the meta- and para-compounds were slowly decomposed.

No reaction could be brought about between formaldehyde and picramide.

L. T. T.

Derivatives of Paradianilidobenzene. By O. Brunck (*Ber.*, **25**, 2715—2722).—It having been shown by O. Fischer and Hepp (Abstr., 1890, 911) that trianilidonaphthalene is readily converted into rosinduline on oxidation, the object of the present work was to ascertain whether, on oxidising amidoparadianilidobenzene [$NH_2 : (NHPh)_2 = 1:2:5$], an induline of the benzene series is formed. The author did not even succeed, however, in preparing the amido-derivative. Calm's paradianilidobenzene (Abstr., 1884, 591) melts at 146° (compare O. Fischer and Wacker, Abstr., 1888, 1286). The diacetyl derivative (Calm, *loc. cit.*), when heated on the water-bath with nitric acid of sp. gr. 1·4, gives a nitro-compound, $NO_2\cdot C_6H_3(NPhAc)_2$, which crystallises from alcohol in pale yellow needles, and melts at 160°. The nitro-compound, when boiled with alcoholic potash, gives a violet compound which may be an azo-derivative; on reduction with tin and hydrochloric acid, it yields a substance having phenolic properties, and this, if heated at 130° with 20 per cent. hydrochloric acid, gives aniline and a carbonaceous residue smelling distinctly of quinone, so that it is perhaps a quinoneoxime. Braudrowsky's diphenylparazophenylene (quinonedianil) is obtained by heating either paradianilidobenzene or its diacetyl derivative with alcoholic potash. The above-mentioned nitrodiacetylparadianilidobenzene, when boiled with alcoholic sulphuric acid, yields a compound which,

when heated with alcoholic ammonium sulphide, gives an *anhydro-base*, $NHPh\cdot C_6H_3<^{NPh}_{N}>CMe$, melting at 162—164°; if, however, the nitro-compound is first reduced, a *basic* substance, $C_{22}H_{19}N_3O$, melting at 180° is produced, which gives the last-mentioned anhydrobase on hydrolysis with alcoholic sulphuric acid.

Diformylparadianilidobenzene, $C_{20}H_{16}N_2O_2$, prepared by boiling paradianilidobenzene with formic acid of sp. gr. 1·2 (10 parts), crystallises from alcohol in white needles, and melts at 168°; when nitrated under the same conditions as the diacetyl derivative (see above), a *dinitro*-derivative melting at 215° is obtained. Calm's dibenzoylparadianilidobenzene (*loc. cit.*) yields a trinitro-derivative melting at 248°. A. R. L.

Condensation Products of the Amidophenols. By E. Haegele (*Ber.*, **25**, 2753—2756).—The author finds that the amidophenols, and especiallly paramidophenol, readily form condensation products with aldehydes and, with rather more difficulty, with ketones. The preparation is similar to that for hydrazones, a dilute acetic solution of the amidophenol being shaken with the aldehyde. Heat is developed, and the condensation product crystallises out. With orthamidophenol, the reaction requires the aid of heat.

Benzylideneparamidophenol, $CHPh{:}N\cdot C_6H_4\cdot OH$, from benzaldehyde and paramidophenol, crystallises in large scales easily soluble in alcohol, but insoluble in water, and melts at 163°. *Hydroxybenzylideneparamidophenol*, $OH\cdot C_6H_4\cdot CH{:}N\cdot C_6H_4\cdot OH$, from salicylaldehyde, forms yellow or orange scales soluble in boiling water and alcohol, and melts at 135°. No phenanthridine derivative could be obtained. Dilute sulphuric acid splits the compound up into its components. *Methoxybenzylideneparamidophenol*, $OMe\cdot C_6H_4\cdot CH{:}N\cdot C_6H_4\cdot OH$, from anisaldehyde, crystallises in yellow prisms melting at 188°. It is soluble in boiling water and in ether or benzene. *Cinnamylidenepar-amidophenol*, $CHPh{:}CH\cdot CH{:}N\cdot C_6H_4\cdot OH$, forms pale green needles, melts at 223°, and is soluble in ether, benzene, and glacial acetic acid, sparingly so in cold water or alcohol. The *dibromo-* additive product forms very dark red needles sparingly soluble in alcohol, insoluble in water, and melts at 287°.

Isopropyleneparamidophenol, $CMe_2{:}N\cdot C_6H_4\cdot OH$, from acetone, crystallises from water in colourless needles melting at 158°. No corresponding condensation product could be obtained from acetophenone.

Hydroxybenzylideneorthamidophenol crystallises in needles melting at 175°. It is sparingly soluble in boiling water and in benzene, more readily in alcohol and in ether. *Methoxybenzylideneorthamidophenol* crystallises from alcohol in yellowish-brown needles melting at 89°. *Cinnamylideneorthamidophenol* crystallises from boiling alcohol in glistening needles, and melts at 79°. It is easily soluble in alcohol and in ether. L. T. T.

Condensation Products of Furfuraldehyde with Bases. By G. de Chalmot (*Annalen*, **271**, 11—14).—A condensation product of

the constitution $C_4OH_3{\cdot}CH{:}NPh$ is formed when aniline is mixed with the molecular quantity of furfuraldehyde. It separates from ether in yellowish crystals, melts at 58°, and boils at 163—164° (uncorr.) under a pressure of 19 mm.; it rapidly turns yellow and then red on exposure to the air, and when heated with aniline hydrochloride, it yields an intensely reddish-violet compound.

The compound of the composition $C_{12}H_{11}NO$, prepared from orthotoluidine in like manner, forms almost colourless crystals, melts at 54—55°, and boils at 171—172° under a pressure of 19 mm.; it turns red on exposure to the air, is decomposed by boiling acids, and combines with aniline and with toluidine yielding red dyes. The condensation product of furfuraldehyde and paratoluidine melts at 43—44°, and resembles the compound just described.

Furfuraldehyde and benzylamine react readily, yielding an oil of the constitution $C_4OH_3{\cdot}CH{:}N{\cdot}CH_2Ph$; this substance boils at 155° under a pressure of 11 mm., and is decomposed by boiling water.

The condensation product of furfuraldehyde and piperidine boils at 157—158·5° under a pressure of 14 mm., and has the composition $C_{15}H_{24}N_2O$; its *hydrochloride*, $C_{15}H_{24}N_2O,2HCl$, is very hygroscopic, and is quickly decomposed by water. F. S. K.

Condensation Products of Furfuraldehyde with Aromatic Bases. By G. J. L. DE CHALMOT (*Amer. Chem. J.*, **14**, 310—314). Furfuraldehyde, aniline, and aniline hydrochloride yield a violet-red crystalline compound, $2C_6H_7N,C_5H_4O_2,HCl$, without elimination of water. Schiff represented the composition of this furfuraniline by the formula $C_4OH_3{\cdot}CH(C_6H_4{\cdot}NH_2,HCl){\cdot}C_6H_4{\cdot}NH_2,H_2O$, but was unable to prepare free furfurandiphenylmethane.

The author obtained only negative results on attempting to obtain the base, although with solutions free from water.

With the corresponding toluidine compound, it was found that on drying for 9 hours at 100—105°, water was lost; the dried substance was no longer crystalline, but behaved towards solvents just like the crystalline compound. It had the composition $C_{19}H_{20}N_2O,HCl$.

Among the products of decomposition obtained on heating to 200° were colourless crystals of an aromatic base.

The author concludes that the water present in the compound is not united to one of the amido-groups, but is simply water of crystallisation. He wishes to reserve the investigation of the reaction between the compound $C_6H_5N{:}C_5H_4O$ and dimethylaniline.

W. T.

Stereoisomerism of Carbodiphenylimide and Carbodiparatolylimide. By C. SCHALL and S. PASCHKOWETZKY (*Ber.*, **25**, 2880—2895).—The authors have succeeded in resolving carbodiphenylimide and carbodiparatolylimide respectively into two modifications (compare Weith, this Journal, 1874, 480; Will, Abstr., 1881, 905; Will and Bielschowsky, *ibid.*, 1882, 1091) by distillation under diminished pressure. The results vary according to the pressure under which the distillation is conducted, also according to the length of time the compounds have been kept after their preparation. See-

ing that the two modifications have the same molecular weights, the authors suggest that they are stereoisomerides, and propose to represent them by the following general configurations  and  .

The following may be cited from the experimental portion:—Carbodiphenylimide (freshly prepared) boils at 218° (30·8 mm.); the distillate solidifies and has a melting point of 136°. When the latter is carefully crystallised from anhydrous benzene, it melts at 158—160°; whilst an oily modification which could not be completely freed from the solvent was obtained from the benzene solution. The oily modification is converted into the solid one on triturating it with alcohol, and when the latter is heated at 110°, the oily modification is formed. The oily modification is converted into carbanilide by boiling it with alcoholic hydrochloric acid, but this reaction takes place much less readily with the solid modification.

Carbodiparatolylimide (freshly prepared) boils at 238° (35 mm.); the distillate subsequently solidifies, and has a melting point of about 60°. When the latter is allowed to remain for 20 hours with dry light petroleum, filtered from the undissolved portion, and the solution evaporated, a modification melting at 49—50° is obtained; whilst when the substance melting at 60° is crystallised from anhydrous ether, and subsequently extracted with boiling light petroleum, a modification melting at 148—149° is isolated. When either of these modifications is distilled under diminished pressure, it is partially converted into the other. Diparatolylcarbamide is formed when the modification of lower melting point is boiled with alcoholic hydrochloric acid, or when that of higher melting point is boiled with acetic acid. A. R. L.

Constitution of Nitrosoazo-compounds. By C. Willgerodt (*Ber.*, **25**, 2661—2664).—Phenylazimidobenzene, dinitrosoazobenzene, and the two nitrodinitrosoazobenzenes, when boiled with a mixture of equal parts of fuming nitric and sulphuric acids for one hour, yield the same compound, namely tetranitrophenylazimidobenzene,

$$C_6H_3(NO_2)_2\cdot N<\begin{matrix}N\\|\\N\end{matrix}>C_6H_2(NO_2)_2.$$

This result points either to the conclusion that: (1.) True nitrosoazo-compounds do not exist, but are azimido-compounds or derivatives of the same; or that (2) nitrosoazo-compounds do exist, but on nitration are converted into azimido-compounds. If the latter conclusion is accepted, then on nitrating dinitrosoazo-compounds, the nitroso-group in the ortho-position relatively to the azo-group is reduced and thus becomes capable of converting the azo- into the azimido-group, and further the nitroso-group in the para-position to the azo-group is oxidised to the nitro-group. On treating mononitromononitroso- and dinitromononitroso-azobenzene with nitric and sulphuric acids, the author obtained tetranitrophenylazoximidobenzene, and not tetranitrophenylazimidobenzene. Against the assumption that nitroso-groups

of nitrosoazo-compounds are oxidised and reduced by boiling with nitro-sulphuric acid, is the fact that the nitroso-group of mononitroso-azo-compounds is not oxidised to a nitro-group by dilute nitric acid, by acetic and chromic acids, by fuming nitric acid, or by nitro-sulphuric acid, and that the nitroso-group of mononitrosoazo-compounds is not reduced by nitro-sulphuric acid. The author concludes that true nitrosoazo-compounds do not exist, but that they are derivatives of azimido-compounds.

The author reserves the study of the two isomeric dinitrophenyl-azimidobenzenes, nitrosoazoxybenzene and symmetrical trinitroso-phenylparabromazobenzene.

Tetranitrophenylazimidobenzene is prepared by boiling phenyl-azimidobenzene, dinitrosoazobenzene, or the two nitrodinitrosoazo-benzenes with 20 times the quantity of nitro-sulphuric acid. The mixture is poured into water and the precipitate extracted with alcohol and crystallised from toluene or acetic acid. From acetic acid, it separates in bright-yellow plates or prisms, and melts at 195—196°. It crystallises from toluene in long, thick prisms containing 2 mols. of toluene, and from benzene in yellowish-white needles containing 2 mols. of benzene. It is sparingly soluble in ether, alcohol, and chloroform.

Tetranitrophenylazoximidobenzene, $C_6H_3(NO_2)_2{\cdot}N_3O{:}C_6H_2(NO_2)_2$, is prepared in a similar way from nitronitroso- and dinitronitroso-azo-benzene. From acetone it is obtained in thin, well formed crystals, from acetic acid in small, measurable crystals, and large, yellow prisms, and from benzene in crystals containing 2 mols. of the hydrocarbon. It decomposes at 192°, is insoluble in ether, sparingly soluble in alcohol and chloroform, and very easily so in acetone. All the solutions are deep-yellow. E. C. R.

Metallic Derivatives of Phenylhydrazine. By G. Martina (*L'Orosi*, **15**, 37—41).—The metallic derivatives of phenylhydrazine described below were obtained by mixing solutions of a metallic salt (1 mol.) and phenylhydrazine (2 mols.). With zinc chloride, the salt $Zn(NHPh{\cdot}NH_2Cl)_2$ is formed. It crystallises in small, white needles which rapidly become brown or flesh-coloured. On adding hydrochloric acid to the mother liquor, no double salt is obtained, but only phenylhydrazine hydrochloride.

With mercuric chloride, a white, flocculent precipitate is formed from which metallic mercury is soon deposited even in the cold. Auric and platinic chlorides are likewise rapidly reduced by phenyl-hydrazine; baric and stannic chlorides are not acted on; stannous chloride is converted into the hydroxide, $Sn(OH)_2$. With cadmium sulphate, a yellowish or orange-coloured salt of the composition $Cd(NHPh{\cdot}NH_2)_2{:}SO_4$ is obtained.

With ferrous sulphate, small, white needles or hard nodules of the composition $Fe(NHPh{\cdot}NH_2)_2{:}SO_4$ are formed. They rapidly turn brown on exposure to the air.

Copper sulphate yields an unstable salt which almost immediately turns black; on warming, the copper is reduced to the metallic state. If the precipitated copper salt is thrown on a filter as soon as it is

formed, it swells up and rapidly decomposes with development of heat. With zinc sulphate, slender needles of the salt

$$Zn(NHPh{\cdot}NH_2)_2{\cdot}SO_4,$$

are obtained, soluble in water and in alcohol. On adding sulphuric acid to the mother liquor, the acid salt, $H_2SO_4{,}Zn(NHPh{\cdot}NH_2)_2{\cdot}SO_4$, is gradually deposited in hard, silvery plates which soon become rose-coloured. With nickel and strontium sulphates, no precipitates are formed. On adding an alcoholic solution of phenylhydrazine to an aqueous solution of lead nitrate, the basic salt, $Pb(OH)NO_3$, is precipitated.

Xylidine forms with zinc chloride the salt $Zn(C_6H_3Me_2{\cdot}NH_2Cl)_2$, which crystallises in tufts of white or pinkish needles, soluble in water and alcohol. It turns brown at 100°. On adding hydrochloric acid to the mother liquor, the hydrochloride of the base is formed. With zinc and cadmium sulphates, double salts are obtained, and on adding sulphuric acid to the mother liquors the acid salts are precipitated. No salts are formed with silver and copper nitrates, whilst with lead nitrate it behaves like phenylhydrazine.

Action of Orthonitrobenzyl Chloride on Phenylhydrazine. By C. Paal and A. Bodewig (*Ber.*, **25**, 2896—2904).—Orthonitrobenzyl chloride and phenylhydrazine react with explosive violence; the action proceeds tranquilly, however, in the presence of a diluent. When the chloride (1 mol.) is added to a solution of phenylhydrazine (2 mols.) in absolute alcohol (4—5 vols.), and the mixture subsequently heated for 3—4 hours on the water-bath, phenylhydrazine hydrochloride separates, and, on adding the product to hot water containing acetic acid and sodium acetate, a red oil is precipitated which consists of orthonitrobenzylphenylhydrazine 50—60 per cent.), bisorthonitrobenzylphenylhydrazine (20—30 per cent.), and orthonitrophenylmethaneazobenzene (5 per cent.), together with a red resin. The oil is extracted with ether, and hydrochloric acid added to the solution, when the hydrochloride of the first-named compound is precipitated; the other two compounds (see below), being devoid of basic properties, remain dissolved, and are separated by fractional crystallisation from glacial acetic acid.

Orthonitrobenzylphenylhydrazine, $NO_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NPh{\cdot}NH_2$, crystallises from alcohol in yellow needles, melts at 72°, and is sparingly soluble in light petroleum, readily so in alcohol and ether; the *hydrochloride* melts at 196—198°, and is partially dissociated by a large excess of water. The *formyl* derivative, $NO_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NPh{\cdot}NH{\cdot}CHO$, obtained by boiling the base for two hours with concentrated formic acid, crystallises from dilute alcohol in lustrous, bright-yellow, flat needles, melts at 141—142°, and is almost insoluble in light petroleum.

Orthamidobenzylphenylhydrazine, prepared by reducing the nitro-base with zinc dust and acetic acid, crystallises from dilute alcohol in flat, white needles or elongated leaflets, melts at 102°, boils at 254°, and is readily soluble in the usual solvents except light petroleum; solutions of its salts are not dissociated by water. The *formyl* derivative is obtained by treating formylorthonitrobenzylphenylhydrazine dissolved

in alcohol with zinc dust and hydrochloric acid at as low a temperature as possible; it crystallises from alcohol in small, white, stellate groups of tables, melts at 157°, and is almost insoluble in water and light petroleum; the formyl group is eliminated on heating with acids and alkalis, and when the compound is heated above its melting point, it yields an *anhydro-base*, $C_6H_4<\begin{matrix}CH_2\cdot NPh\\ N=CH\end{matrix}>NH$.

Bisorthonitrobenzylphenylhydrazine, $N_2HPh(CH_2\cdot C_6H_4\cdot NO_2)_2$, crystallises from alcohol in red needles, melts at 128°, and is sparingly soluble in ether and alcohol, readily so in benzene. It remains unaltered when boiled with acetic anhydride or when its solutions are heated with mercuric oxide, and yields, on reduction, amorphous substances which were not further examined.

Orthonitrophenylmethaneazobenzene, $NO_2\cdot C_6H_4\cdot CH_2\cdot N_2Ph$, is isolated from the final mother liquor obtained in crystallising the last-described compound; it crystallises from alcohol in dark red needles, melts at 154°, and on reduction with zinc dust and acetic acid, gives a *base*, $C_{13}H_{13}N_3$, which crystallises in flat, white needles, and melts at 218—220°; it is now being further investigated. A. R. L.

α-Phenylhydrazidopropionic Acid. By A. Reissert (*Ber.*, **25**, 2701—2705).—The compound described by the author (Abstr., 1884, 1152) as asymmetrical α-phenylhydrazidopropionic acid is, in accordance with v. Miller and Plöchl's statement (this vol., p. 1196), the symmetrical derivative obtained by Fischer and Jourdan (Abstr., 1884, 53), and subsequently by Japp and Klingemann (Trans., 1888, 535). The melting point previously given by the author (*loc. cit.*) is too high.

Ethyl phenylhydrazidopropionate, also described by the author (*loc. cit.*), is an oil which, if left for a time in the desiccator, undergoes oxidation to ethyl phenylhydrazinepyruvate. On boiling it with concentrated hydrochloric acid for four hours, α-anilidopropionic acid, phenylhydrazinepyruvic acid, and ammonia are produced.

α-Nitrosoanilidopropionic acid, NO·NPh·CHMe·COOH, is prepared by dissolving α-anilidopropionic acid (16·5 grams) in concentrated hydrochloric acid (14 grams), and, after diluting with water, adding to the cooled mixture a concentrated solution of potassium nitrite (8·5 grams). When purified by repeated dissolution in ammonia and reprecipitation with acid, it melts at 88·5° (corr.), and is very readily soluble in most solvents except light petroleum. The author hopes, by the reduction of this nitroso-derivative, to obtain the unknown asymmetrical α-phenylhydrazidopropionic acid. A. R. L.

Alkyl Derivatives of Hydroxylamine. By R. Behrend and E. König (*Annalen*, **271**, 92—94).—The authors describe further quantitative experiments, which afford additional proofs that the oxidation products of benzylnitrobenzylhydroxylamine and of nitrobenzylbenzylhydroxylamine are identical, and are formed in the same quantities in both cases (compare Abstr., 1891, 1032). F. S. K.

Quinoneoxime Ethers. By J. L. Bridge (*Amer. Chem. J.*, **14**, 276—286).—Quinoneoxime methoxide, $C_6H_4O{:}NOMe$, was prepared

by treating silver nitrosophenol suspended in ether with $1\frac{1}{4}$ times the calculated amount of methyl iodide. The dark brown, tarry mass obtained by spontaneous evaporation of the ethereal filtrate was extracted with hot light petroleum, and the solution decolorised with charcoal, when it yielded, on concentration, flat, yellow needles melting at 83° after recrystallisation. It dissolves readily in organic solvents and in hot water, and in considerable amount in cold water or light petroleum, has a strong, pleasant, ethereal odour, and is readily volatile with steam; if not quite pure, it quickly decomposes, like quinone, turning first green and then dark brown.

The same substance is formed by gently warming a solution of sodium nitrosophenol in methyl alcohol with methyl iodide. About 0·2 gram of dark red needles, probably a polymeric nitrosophenol, are obtained for each gram of nitrosophenol taken. This substance is insoluble in organic solvents, but dissolves in alkalis and ammonia with a deep red coloration, and is precipitated unchanged by acids or carbonic anhydride. It begins to decompose at 250° without melting. The analyses made did not yield concordant results, as it burns with very great difficulty. Nitric acid (sp. gr. 1·4) converts it quantitatively into 1 : 2 : 4-dinitrophenol melting at 114°. Tin and hydrochloric acid reduce it to paramidophenol melting at 180°.

The methoxide is quantitatively converted into a *dibromide*, $C_6H_4O{:}NOMe,Br_2$, by addition of bromine (1 mol.) to the chloroform solution. The reaction is complete in half an hour, and no hydrogen bromide is noticed. It is colourless, and crystallises from chloroform in four-sided plates, softens at 113°, and melts at 118° without decomposition.

Quinoneoxime ethoxide, $C_6H_4O{:}NOEt$, is obtained in a similar manner to the methoxide; it crystallises in yellow, rhombic or hexagonal plates, melts at 30°, and has a strong ethereal odour. It is easily volatile with steam, and dissolves readily in all solvents, being least soluble in cold water and light petroleum. The methoxide and ethoxide do not resemble nitrosophenol, but show a very close resemblance to benzoquinone. The conclusive proof that they are compounds of quinoneoxime, and not of nitrosophenol, is that α-benzylhydroxylamine converts quinone quantitatively into the compound $C_6H_4O{:}NO{\cdot}CH_2Ph$, which is identical in every respect with the compound obtained from sodium or silver nitrosophenol and benzyl chloride.

Quinoneoxime acetate, $C_6H_4O{:}NOAc$, is obtained by treating silver nitrosophenol suspended in much absolute ether with freshly-distilled acetic chloride. The compound formed crystallises in light yellow needles, and melts at 107°. It is but slightly soluble in water, and odourless; its solutions in ether and in alcohol are green, like those of nitrosophenol. If dry and finely powdered it causes sneezing.

Ethyl quinoneoximecarboxylate, $C_6H_4O{:}N{\cdot}O{\cdot}COOEt$, is obtained when silver nitrosophenol and ethyl chloroformate, in molecular proportion, are suspended in absolute ether, and gently heated for a short time; it crystallises in yellow plates melting at 110°.

Quinoneoxime benzoate, $C_6H_4O{:}NOBz$. is obtained by treating dry sodium or silver nitrosophenol with benzoic chloride, or, better, by shaking an alkaline solution of nitrosophenol with benzoic chloride.

It forms pale yellow needles melting at 172—174°. The solution in alcohol is green, but its colour is not so marked as that given by nitrosophenol or the acetate.

Quinoneoxime benzoxide, $C_6H_4O{:}NO{\cdot}CH_2Ph$, is formed when silver nitrosophenol, suspended in absolute ether, is heated for several hours with benzyl chloride ($\frac{3}{4}$ mol.) until the smell of the latter has disappeared; it crystallises in yellow, rectangular or rhombic plates and melts at 63·5°. The same substance is formed by heating sodium nitrosophenol dissolved in alcohol with benzyl chloride. It is insoluble in water, but readily soluble in all organic solvents except light petroleum. It has no odour. When treated with tin and hydrochloric acid, it is converted into paramidophenol, whilst much benzyl chloride is also formed. It is also obtained quantitatively by treating quinone (1 gram) dissolved in water (250 c.c.) with the calculated amount of α-benzylhydroxylamine hydrochloride dissolved in water containing a few drops of hydrochloric acid.

The results obtained show that the properties and stability of quinone and its derivatives depend entirely on the negative or positive condition of the molecule. W. T.

Action of Amido-Bases on Sodium Glyoxalsulphonate. By O. Hinsberg (*Ber.*, **25**, 2545—2547).—The author has already shown (Abstr., 1888, 372) that whereas aniline acts on sodium glyoxalsulphonate with formation of anilidoacetanilide, the naphthylamines yield sulphonic acids of naphthindoles. Benzylamine behaves in a similar manner to aniline, yielding the *benzylamide of benzylamidoacetic acid*, $CH_2Ph{\cdot}NH{\cdot}CO{\cdot}CH_2{\cdot}NH{\cdot}CH_2Ph$, which forms an oil, but yields with hydrochloric acid a salt, crystallising in colourless plates. Ethyl-β-naphthylamine, on the other hand, yields *sodium ethyl-β-naphthindolesulphonate*, $C_{14}H_{12}NSO_3Na$, which crystallises in slightly yellowish needles, and is decomposed by hydrochloric acid with formation of a substance free from sulphur, the latter being probably *ethyl-β-naphthoxindole*, $C_{10}H_6{<}\overset{NEt}{\underset{CH_2}{>}}CO$. H. G. C.

Action of Acetic Chloride on Orthohydroxyaldehydes. By W. P. Bradley and F. B. Dains (*Amer. Chem. J.*, **14**, 293—300).—Parachlorosalicylaldehyde was dissolved in a slight excess of glacial acetic acid, and to it was added half its weight of acetic chloride. The reaction was immediate, with evolution of much heat; it was completed by heating on the water-bath after it had been left for some time. By pouring into water, dichlorodisalicylaldehyde, together with some unchanged chlorosalicylaldehyde, was precipitated; the latter substance was removed by treatment with dilute alkali. The yield averages 60—70 per cent. of the theoretical. From a hot concentrated solution in alcohol, fine, white, silky needles of dichlorodisalicylaldehyde were obtained; from more dilute solutions, it comes down in slender, mossy filaments. Its melting point is 172°. It is easily soluble in alcohol, ether, acetic acid, benzene, chloroform, and carbon bisulphide, less soluble in light petroleum. It easily dissolves

in concentrated sulphuric acid, giving an amber-coloured solution, which, when poured into water, deposits quantitatively parachlorsalicylaldehyde.

Dibromo- and dichloro-salicylaldehyde gave no condensation products with acetic chloride, even in a sealed tube at 115—130°.

Paranitrosalicylaldehyde, when treated in the same way as the chloro-compound, does not give a condensation product, but when heated at 100° in a sealed tube, a small quantity of dinitrosalicylaldehyde is obtained. It dissolves with difficulty in alcohol, acetic acid, ether, chloroform, carbon bisulphide, and light petroleum, and but little more freely in benzene. The sulphuric acid solution, when poured into water, gives paranitrosalicylaldehyde.

Orthonitrosalicylaldehyde appears to be unaffected by acetic chloride under any conditions.

α-Aldehydo-β-naphthol condenses very readily under the action of acetic chloride, with development of heat. The yield is nearly quantitative. The product, *β-diorthohydroxy-α-naphthaldehyde*, dissolves with difficulty in the ordinary solvents. From benzene or acetic acid, it is deposited in small, hard, nearly white crystals, melting at 241°. The solution in sulphuric acid is dark red, with a green fluorescence; on diluting it with water, α-aldehydo-β-naphthol is deposited.

Paramethylsalicylaldehyde gives a nearly quantitative yield of paradimethyldisalicylaldehyde. The pure compound melts at 141°; its molecular weight, determined by Raoult's method, using acetic acid as solvent, was 251·2; the calculated value is 254. It is easily soluble in most solvents, but dissolves sparingly in light petroleum. It crystallises from petroleum in beautiful, oblong tables, pointed at the ends. It is easily volatile with steam. Attempts to oxidise the methyl groups to carboxyl have failed; protracted boiling with a 15 per cent. alkaline solution of permanganate produced no effect.

Acetic chloride has no action on orthoaldehydosalicylic acid.

It appears probable that acetic chloride can secure the quantitative condensation of all orthohydroxyaldehydes in which only hydrocarbon groups are joined directly to the benzene ring. The introduction of negative groups hinders or entirely prevents condensation. The presence in the molecule of a chlorine or bromine atom reduces the yield 30—40 per cent. A single nitro-group in the para-position nearly prevents condensation, whilst a carboxyl- or nitro-group in the ortho-position, or the presence of two halogen atoms, prevents it altogether. W. T.

New Method for the Preparation of some Aromatic Nitroketones. By K. Lange and A. Zufall (*Annalen*, **271**, 1—11).—The compounds of the general formula $CCl_3{\cdot}CHR_2$, obtained by the condensation of chloral with aromatic hydrocarbons, are converted into unsaturated dichloro-compounds of the constitution $CCl_2{:}CR_2$ by alcoholic potash; when these unsaturated compounds are treated with nitric acid, they are decomposed, yielding, in some cases, not only unsaturated nitro-derivatives of the dichloro-compounds, but also

saturated nitro-ketones; a saturated nitro-ketone could not, however, be obtained from dichlorodixylylethylene, $CCl_2{:}C(C_6H_3Me_2)_2$.

A *dinitro* compound of the constitution $CCl_2{:}C(C_6H_4{\cdot}NO_2)_2$ is formed, together with dinitrobenzophenone, when dichlorodiphenylethylene is gradually added to well-cooled, concentrated nitric acid, the solution kept for a short time and then poured on to ice; the acid solution is decanted from the yellow, resinous precipitate, the latter extracted with hot alcohol, and the residue recrystallised from glacial acetic acid; in this way the dinitro-compound is obtained in yellow needles melting at 172°. From the acid mother liquors, dinitrobenzophenone is slowly deposited in crystals; this compound melts at 187—188°, and is identical with the paradinitrobenzophenone described by Städel and Haase (Abstr., 1890, 1422); it can be obtained by treating the dichlorodinitro-compound described above with concentrated nitric acid.

Dinitroditolyl ketone, $CO(C_6H_3Me{\cdot}NO_2)_2$, prepared by dissolving dichloroditolylethylene, $CCl_2{:}C(C_6H_4Me)_2$, in well-cooled concentrated nitric acid, crystallises from glacial acetic acid in yellow needles, melts at 144°, and dissolves freely in benzene and toluene, but is more sparingly soluble in acetone and alcohol, and insoluble in light petroleum. The *hydrazone*, $C_{21}H_{18}N_4O_4$, is a red, crystalline compound melting at 169—170°.

Diamidoditolyl ketone, $CO(C_6H_3Me{\cdot}NH_2)_2$, is formed when the dinitro-compound is treated with the theoretical quantity of stannous chloride in glacial acetic acid solution; it separates from dilute alcohol in yellow crystals and melts at 171—172°. The *diacetyl* derivative, $C_{19}H_{20}N_2O_3$, crystallises in colourless needles and melts at 196—197°. The *dipiperidide*, $CO(C_6H_3Me{\cdot}N{:}N{\cdot}NC_5H_{10})_2$, prepared by treating the diazotised diamido-compound with piperidine, crystallises from alcohol and acetone in yellowish-red needles.

When dichloroditolylethylene is oxidised with chromic acid in glacial acetic acid solution, it yields paratolylbenzoic acid (m.p. 224—225°), so that in the dinitro-ketone described above the methyl groups are in the para-position relatively to the carbonyl radicle. A hydroxyketone of the composition $CO(C_6H_3Me{\cdot}OH)_2$ is formed when a sulphuric acid solution of diamidoditolyl ketone is diazotised and the mixture then boiled; it sublimes in lustrous plates, but without melting. When this dihydroxy-ketone is fused with potash, it is converted into a hydroxytoluic acid, $C_8H_8O_3$, which melts at 206—207°, and does not give a coloration with ferric chloride; the constitution of this acid is probably [COOH : OH : Me = 1 : 3 : 4] and consequently that of the dinitro-ketone [CO : NO_2 : Me = 1 : 3 : 4].

F. S. K.

Iodosobenzoic Acid. By V. Meyer and W. Wachter (*Ber.*, **25**, 2632—2635).—Orthiodobenzoic acid dissolves in fuming nitric acid with evolution of heat; on heating the solution for some seconds, cooling, and pouring into water, a precipitate of *iodosobenzoic acid*, $C_7H_5IO_3$, separates, and, when crystallised from boiling water, is obtained in satiny leaflets or granular crystals which melt at 209°, with evolution of gas. The acid acts as a strong oxidising agent, and may be estimated by heating in a closed tube at 100° with

potassium iodide and dilute sulphuric acid in the absence of air, iodobenzoic acid and iodine are thus liberated, and the latter, on titration with standard thiosulphate solution, indicates the amount of the new acid present. On heating with concentrated hydrochloric acid, chlorine is liberated. When dissolved in ammonia solution and warmed with zinc-dust, it readily yields benzoic acid. The acid forms salts with alkalis, and dissolves in aqueous ammonia; on adding ammoniacal silver nitrate to this solution, however, pure iodosobenzoic acid is reprecipitated. Its constitution may be represented either as

$$COOH\cdot C_6H_4\cdot I{:}O \text{ or as } \begin{array}{l} CH \\ CH \\ CH \end{array}\!\!\begin{array}{c} \diagup CH \diagdown \\ \| \quad O \quad | \\ \diagdown CH \diagup \end{array}\!\!\begin{array}{l} CI \\ \| \\ C\cdot COOH \end{array};$$

the former is, however, the more probable constitution. The acid decolorises permanganate solution, and, when warmed with aniline or orthamidobenzoic acid dissolved in glacial acetic acid, deep brown solutions are obtained. The reactions involved in these changes are under examination.

Orthobromobenzoic and meta- and para-iodobenzoic acids, on treatment with fuming nitric acid, simply undergo nitration.

W. J. P.

Hexachlorometadiketohexene. The Action of Chlorine on 1, 3, 5-Dihydroxybenzoic Acid. By T. Zincke and O. Fuchs. (*Ber.*, **25**, 2680—2698).—Dichloro- and trichloro-dihydroxybenzoic acids are obtained when dihydroxybenzoic acid, dissolved in acetic acid, is treated with the quantity of chlorine requisite to form the trichloro-acid. The two acids cannot be separated by fractional crystallisation, but the acetyl compounds are easily separated by crystallisation from a mixture of benzene and light petroleum, in which the trichloro-derivative is sparingly soluble.

Hexachlorometadiketohexene is easily prepared by saturating a mixture of dihydroxybenzoic acid (1 part) and acetic acid (5 parts) with dry chlorine, allowing the mixture to remain 24 hours, again saturating with chlorine, and allowing it to remain 24 hours, and distilling off the acetic acid at 90—100° under diminished pressure. The crude compound is purified by distillation under a pressure of 11—15 mm.

2 : 4- or 2 : 6-*Dichlorodihydroxybenzoic acid*, $C_6HCl_2(OH)_2\cdot COOH$, crystallises in short, colourless needles, melts at 202°, and is sparingly soluble in light petroleum and hydrochloric acid, but easily in other solvents. The *acetyl* compound crystallises in beautiful, colourless crystals, and melts at 179°.

Trichlorodihydroxybenzoic acid, $C_6Cl_3(OH)_2\cdot COOH$, crystallises in slender, white needles, melts at 192°, and is easily soluble in alcohol, ether, benzene, and water. The *acetyl* compound crystallises in slender needles, and melts at 207°. The *methyl* salt of the acetyl compound crystallises from dilute alcohol in thick, colourless needles, and melts at 116°.

Hexachlorometadiketohexene, $CO<\begin{matrix}CCl_2\cdot CO\\CCl:CCl\end{matrix}>CCl_2$, a colourless, crystalline mass, melts at 115°, distils at 159—160° under 13—15 mm.,

has a penetrating odour, causing tears, and is easily soluble in ether benzene, and chloroform, sparingly so in light petroleum. When boiled with water, it yields a ketone of the formula $C_5H_2Cl_6O$. It liberates iodine from potassium iodide, yields tetrachlororesorcinol when reduced, is not attacked by chlorine at 180—200°, does not give a characteristic compound with aniline, and with ammonia yields the acid amide $C_6HCl_5O_2{\cdot}NH_2$. When treated with phosphorus pentachloride, it yields hexachlorobenzene and the ethereal salt

$$C_6Cl_5O{\cdot}PO(OH)_2$$

(m. p. 203°).

Tetrachlororesorcinol, $C_6Cl_4(OH)_2$, is obtained by reducing the hexachlorodiketone, dissolved in 10 parts of acetic acid, with stannous chloride. It crystallises in long, colourless needles, melts at 141°, is easily soluble in alcohol, ether, benzene, and acetic acid, somewhat easily in hot water, and sparingly in dilute hydrochloric acid. The authors were unable to obtain a quinone from it. The *acetyl compound* crystallises in white needles, melts at 145°, is insoluble in water, and tolerably soluble in acetic acid, ether, alcohol, and benzene.

Dichloracetyltetrachlorocrotonic acid,

$$CHCl_2{\cdot}CO{\cdot}CCl{:}CCl{\cdot}CCl_2{\cdot}COOH,$$

is obtained by adding a cold solution of the hexachloroketone in acetic acid (5 to 6 parts) to 4—5 times the volume of sodium acetate (1 part salt to 10 parts water). The mixture is allowed to remain a few minutes, strongly acidified with hydrochloric acid, and the product crystallised from hot petroleum. It crystallises in long, colourless scales, melts at 112°, is easily soluble in ether, alcohol, and benzene, sparingly in water, and, when heated with water, yields the ketone, $C_5Cl_6OH_2$; the latter is also obtained by dry distillation of the acid. When treated with aniline, carbonic anhydride is evolved, and the anilide, $C_5H_2Cl_5O{\cdot}NHPh$, is formed. The *methyl* salt crystallises in colourless tablets, melts at 93°, and is easily soluble in alcohol, ether, &c. The *amide*, $CHCl_2{\cdot}CO{\cdot}CCl{:}CCl{\cdot}CCl_2{\cdot}CONH_2$, is obtained by passing ammonia into a solution of the hexachloroketone in benzene. It crystallises in white, silky needles, melts at 181°, and is easily soluble in alcohol and acetic acid.

The *ketone*, $CHCl_2{\cdot}CO{\cdot}CCl{:}CCl{\cdot}CHCl_2$, is obtained by diluting with water an acetic acid solution of the preceding acid, and distilling the mixture with steam as long as oil comes over, or by boiling the acid with water in a reflux apparatus as long as carbonic anhydride is evolved, and distilling with superheated steam; or by heating the acid by itself and distilling the product under diminished pressure. It is a yellow, highly refractive oil, boils at 147—148° under a pressure of 20—25 mm., and has a penetrating odour, causing tears.

The *azine*, $C_5H_2Cl_3{<}\overset{N-}{\underset{NH}{}}{>}C_6H_4$, is obtained if an alcoholic solution of the ketone and orthophenylenediamine is left for a time at the ordinary temperature; it crystallises in broad, yellow needles, melts at 126°, and is insoluble in water, tolerably soluble in hot acetic acid, ether and benzene, and less so in alcohol or petroleum. The *anilide*,

$C_5H_2Cl_5O{\cdot}NHPh$, is obtained by adding excess of aniline to a solution of the ketone in acetic acid; it crystallises in short, lustrous, yellow needles, melts at 89°, and is easily soluble in ether, acetic acid, benzene, and light petroleum, less so in alcohol, and insoluble in water.

Trichloroacetyltetrachlorocrotonic acid,

$$CCl_3{\cdot}CO{\cdot}CCl{:}CCl{\cdot}CCl_2{\cdot}COOH,$$

is obtained by treating the hexachlorometadiketone with a dilute solution of chloride of lime. It crystallises from hot petroleum in colourless scales or thick needles, from a mixture of ether and petroleum in large, lustrous, monoclinic crystals, melts at 117°, and is easily soluble in alcohol, ether, benzene, and acetic acid, sparingly so in water and petroleum. When boiled with water, carbonic anhydride is evolved, and the ketone C_5HCl_7O is formed. With aniline, it yields the anilide $C_5HCl_6O{\cdot}NHPh$, and is decomposed by alkalis and acids yielding chloroform and the bibasic acid $C_5H_2Cl_4O_4$. When heated alone, it yields the pentene-ketone C_5Cl_6O, together with other products. The *methyl salt* crystallises in thick, colourless scales, melts at 90°, and is easily soluble in the ordinary solvents.

The *ketone*, $CCl_3{\cdot}CO{\cdot}CCl{:}CCl{\cdot}CHCl_2$, is obtained by heating the preceding compound with water. It is a bright yellow, strongly refractive liquid, boils at 182—185° under 13—15 mm. pressure, and has a penetrating smell, causing tears. When treated with alkali, it yields chloroform and an acid which is probably a tetrachlorocrotonic acid. The *azine*, $C_5HCl_6{\lessdot}\overset{N-}{NH}{>}C_6H_4$, crystallises from alcohol in yellow needles, melts at 149°, and is tolerably soluble in benzene, ether, and acetic acid, less so in petroleum and alcohol, and insoluble in water. The *anilide*, $C_5HCl_6O{\cdot}NHPh$, crystallises from hot alcohol in beautiful, yellow needles, melts at 134°, and is somewhat sparingly soluble in alcohol and light petroleum, more so in ether, benzene, and acetic acid.

The ketonic acid $C_6HCl_7O_3$, when heated under the ordinary pressure, yields compounds of the formula C_5Cl_6O, and, by distilling the product under diminished pressure, a colourless, refractive oil is obtained which boils at 148—150° under 12—15 mm. pressure. If the oil is distilled a few times under the ordinary pressure, and then left for a time, colourless crystals are obtained which are identical with those of the isomeric ketone described by Küster and Zincke (*Ber.*, **23**, 2207). The oil dissolves in sodium hydroxide, with an odour of chloroform. When hydrochloric acid is added to the alcoholic solution, pentachloropentolic acid, $C_5Cl_5HO_2$, is formed.

Tetrachloroglutaconic acid, $COOH{\cdot}CCl_2{\cdot}CCl{:}CCl{\cdot}COOH$, is obtained by dissolving the acid $C_6HCl_7O_3$ in sodium carbonate, and adding a dilute solution of sodium hydroxide as long as a turbidity is produced; the mixture is then acidified with hydrochloric acid and extracted with ether. It crystallises in colourless tablets and plates, melts at 109—110°, and is easily soluble in the ordinary solvents, with the exception of petroleum. The *ammonium*, *barium*, and *calcium salts* are easily soluble. The *methyl salt* is a liquid. E. C. R.

$\alpha\beta$-Dichlorocinnamic Acid (Phenylpropiolic Acid Dichloride). By C. Nissen (*Ber.*, **25**, 2664—2667).—$\alpha\beta$-Dichlorocinnamic acid, CPhCl:CCl·COOH, is prepared as described by Roser and Haseloff (*Annalen*, **247**, 146) by passing chlorine into a chloroform solution of phenylpropiolic acid as long as it is absorbed. Roser and Haseloff have only prepared the crude acid. The pure acid is obtained by drying the crude product on porous plates and precipitating it from the chloroform solution by petroleum. It crystallises in beautiful leaflets, has a very faint odour, melts at 120—121°, is easily soluble in alcohol, ether, chloroform, benzene, and acetic acid, but insoluble in light petroleum and cold water. When pure, it yields a colourless solution with soda, but a trace of impurity causes the solution to turn purplish-red. The author was unable to obtain a stereoisomeric acid from the crude product similar to the acid obtained by Roser and Haseloff by the action of bromine on phenylpropiolic acid. By extracting with ether the porcelain plates used in the purification, an oil is obtained which is completely soluble in soda, but is not a dichlorocinnamic acid. The *ammonium salt* crystallises in long needles. The solution of the salt gives no precipitate with calcium, barium, or magnesium salts ; with lead acetate, it gives a white precipitate. The *silver salt* crystallises in white needles, and is soluble in boiling water. The *methyl salt* is a colourless oil. The author was unable to obtain allocinnamic acid by eliminating the chlorine from dichlorocinnamic acid. The chlorine is only eliminated by boiling with zinc and alcohol for 20 hours, and the acid thus obtained is cinnamic acid. Under these conditions, if allocinnamic acid were formed, it would be converted into cinnamic acid.

The author has obtained β-dibromocinnamic acid in beautiful, yellow prisms. The crystals belong to the rhombic system ; $a : b : c = 0{\cdot}9573 : 1 : 0{\cdot}5244$. E. C. R.

Asymmetrical Amidoisophthalic Acid. By R. Loewenherz (*Ber.*, **25**, 2795—2798).—The author endeavoured to obtain an acid of the constitution $C_{12}H_6(NH_2)_2(COOH)_2$, by the oxidation of acetylorthotolidine, but obtained instead, asymmetrical *acetylamidoisophthalic acid*, $NHAc{\cdot}C_6H_3(COOH)_2$, which separates from hot water in colourless crystals, decomposes at 270°, is sparingly soluble even in hot water, but more readily in alcohol. When hydrolysed with a mixture of 3 vols. of sulphuric acid and 2 vols. of water, it is converted into *amidoisophthalic acid*, $NH_2{\cdot}C_6H_3(COOH)_2$, which melts above 300°, and on diazotisation and boiling with water yields the hydroxyisophthalic acid described by Jacobsen (Abstr., 1878, 583). The same acetylamidoisophthalic acid was obtained by Hofmann (this Journ., 1877, i, 90) from metaxylidine, but he was unable to hydrolyse it with hydrochloric acid, whereas the hydrolysis proceeds readily with sulphuric acid of the strength given above.

As the oxidation did not yield diphenyldiamidodicarboxylic acid, the author prepared this acid from orthonitrobenzoic acid (compare Griess, Abstr., 1888, 589), which was boiled with aqueous potash and zinc dust until colourless, and the resulting hydrazo-compound converted into the isomeric *diphenyldiamidodicarboxylic acid*,

$C_{12}H_6(NH_2)_2(COOH)_2$ [= 2 : 2′ : 4 : 4′], by means of boiling hydrochloric acid. This compound has very feebly basic properties, the salts with acids being decomposed by water. An attempt was made to convert it into a diphenyltetracarboxylic acid by means of Sandmeyer's reaction, but without success; this acid has, however, been obtained by the oxidation of ditolyldicarboxylic acid, and will be described in a later paper. H. G. C.

Chlorodurenesulphonic Acid. By A. Töhl (*Ber.*, **25**, 2759—2761).—The author finds that, like sulphuric acid (this vol., p. 968), crystalline fuming sulphuric acid yields with chlorodurene, chloropentamethylbenzene and chlorotrimethylbenzenesulphonic acid. By the action of chlorosulphuric acid on chlorodurene, *chlorodurenesulphonic acid*, $C_{10}H_{12}Cl{\cdot}SO_3H$, is formed. This crystallises from benzene in scales, melting at 136°. The *barium* salt with 1 mol. H_2O is sparingly soluble in water, forms six-sided rhombic plates, and melts with decomposition at 150°. The *potassium* salt with 1 mol. H_2O gives sparingly soluble scales, the *sodium* salt scales free from water. The *sulphochloride* crystallises from light petroleum in six-sided rhombic plates melting at 53—54°, the *sulphonamide* in scales melting at 180—181°. During the preparation of the acid, a compound was obtained composed of 1 mol. sulphonic acid and 2 mols. sulphochloride in the form of short needles melting at 91—92°. L. T. T.

Formation of Substituted Indoles. By A. Bischler (*Ber.*, **25**, 2860—2879).—The author concludes from the experiments to be described that the formation of 2′-phenylindole from phenylacetanilide and aniline (Möhlau, Abstr., 1883, 342; E. Fischer and Schmitt, *ibid.*, 1888, 698) takes place as follows:—

$$COPh{\cdot}CH_2{\cdot}NHPh + C_6H_5NH_2 =$$

$$H_2O + CPh(NHC_6H_5){:}CH{\cdot}NHPh = CPh{\leqslant}\begin{matrix}CH\\NH\end{matrix}{>}C_6H_4 + NH_2Ph.$$

Phenylacetanilide, prepared by triturating bromacetophenone (1 mol.) with aniline (2 mols.) and alcohol, agrees with Möhlau's description (*loc. cit.*). *Phenylacetorthotoluidide*, $COPh{\cdot}CH_2{\cdot}NH{\cdot}C_6H_4Me$, obtained in the same manner from bromacetophenone and orthotoluidine, separates from benzene in flat, yellow crystals, and melts at 89°; the *hydrochloride* forms colourless needles, and decomposes when boiled with water; whilst the *acetyl* derivative, $COPh{\cdot}CH_2{\cdot}NAc{\cdot}C_6H_4Me$, crystallises in white needles, and melts at 92°. *Phenylacetoparatoluidide* crystallises from alcohol in bright yellow prisms, melts at 127°, and yields an *acetyl* derivative melting at 89°. *Phenylacetometachloranilide*, $COPh{\cdot}CH_2{\cdot}NH{\cdot}C_6H_4Cl$, prepared from bromacetophenone and metachloraniline, forms faintly yellow, felted needles, and melts at 138°; the *acetyl* derivative melts at 82°.

2′-Phenylindole is obtained by boiling either phenylacetanilide or phenylacetorthotoluidide with aniline; the nitroso-derivative melts at 247° (compare Fischer and Schmitt, *loc. cit.*). 1-*Methyl*-2′-*phenylindole* is formed when either phenylacetanilide or phenylacetortho-

toluidide is boiled with orthotoluidine. It boils at 250° (10 mm.); the distillate solidifies, and when crystallised from alcohol, the compound melts at 118—119°; it gives a violet-blue pine splinter reaction. The *picrate* melts at 126°, and the *nitroso*-derivative melts at 232°. Phenylacetoparatoluidide, when heated with orthotoluidine, yields a methylphenylindole melting at 112·5°. *3-Methyl-2′-phenylindole* is obtained by boiling either phenylacetanilide or phenylparatoluidide with paratoluidine. It crystallises from benzene or alcohol in white leaflets, melts at 213°, and gives a violet-blue pine splinter reaction; the *picrate* melts at 135°, and the nitroso-derivative at 262°.

2′-Phenylchlorindole [Cl = 2 or 4] is obtained from phenylacetylmetachloranilide (1 mol.), and metachloraniline (2 mols.), or from phenylacetylorthotoluidide (1 mol.), and metachloraniline (2 mols.). It forms small leaflets, melts at 181—182°, gives a violet-blue pine splinter reaction, and is almost insoluble in light petroleum. The *picrate* melts at 127°, and the *nitroso*-derivative melts at 228—229°.

A. R. L.

Carbazole. By G. Pulvermacher and W. Loeb (*Ber.*, **25**, 2766—2767).—By heating a 40 per cent. formaldehyde solution, or trioxymethylene, with carbazole in closed tubes at 100°, the authors obtained *methylenecarbazole*, $CH_2(NC_{12}H_8)_2$, crystallising in long, white, silky needles, which are still solid at 280°. It is a very stable, basic substance, soluble in boiling aniline, but insoluble in the usual solvents. The *picrate* is crystalline. It is not decomposed by concentrated hydrochloric acid even at 190°. Strong nitric acid yields a *tetranitro*-derivative soluble in glacial acetic acid, from which it crystallises in yellow scales. It is acid in properties, forming red crystalline *sodium* and *potassium* derivatives. Zinc and acetic acid appear to cause the reduction of all four nitro-groups.

L. T. T.

Orthotolidinedisulphonic Acid. By J. Helle (*Annalen*, **270**, 359—375).—The compounds described in this paper were prepared by methods similar to those employed by Limpricht (Abstr., 1891, 929) and Limpricht and Meyer (this vol., p. 973), in the case of the benzidine derivatives.

Orthotolidinedisulphonic acid,

$$\overset{6}{SO_3H}\cdot C_6H_2\overset{3}{Me}(\overset{4}{NH_2})\cdot C_6H_2\overset{3'}{Me}(\overset{4'}{NH_2})\cdot\overset{6'}{SO_3H},$$

is obtained by heating orthonitrotoluenesulphonic acid with soda and zinc dust until the solution becomes colourless; it crystallises in colourless, microscopic needles, containing when air dried $1\frac{1}{2}$ mols. H_2O, and is insoluble in alcohol, ether, and glacial acetic acid, and only very sparingly soluble in hot water (compare Bender and Schultz, Abstr., 1887, 268). The potassium hydrogen salt crystallises in needles with 3 mols. H_2O; the barium salt crystallises with 5 mols. H_2O. The *tetrazo*-derivative, $C_{14}H_{10}N_4S_2O_6$, crystallises in well-defined microscopic needles, explodes at 86°, and is almost insoluble in cold water; it seems to crystallise with 1 mol. H_2O.

Ditolyldisulphonic acid, $SO_3H\cdot C_6H_3Me\cdot C_6H_3Me\cdot SO_3H$, is obtained when the tetrazo-derivative just mentioned is boiled with alcohol

and finely-divided copper; it crystallises in yellowish needles, and is very readily soluble in water, but more sparingly in alcohol, and insoluble in ether. The normal *potassium* salt forms readily soluble, hexagonal, anhydrous plates, but the acid salt contains water of crystallisation. The *barium* salt, $C_{14}H_{12}S_2O_6Ba + 5H_2O$, crystallises in rhombic plates, and is rather sparingly soluble in water. The *chloride*, $C_{14}H_{12}S_2O_4Cl_2$, separates from chloroform or benzene in well-defined rhombic prisms, and melts at 228—229°. The *amide*, $C_{14}H_{12}S_2O_4(NH_2)_2$, crystallises from alcohol, in which it is only sparingly soluble, in microscopic needles, which seem to contain 1 mol. C_2H_6O; it decomposes at a temperature above 360°, but without melting.

A *tolidinesulphonic acid*, which has probably the constitution $SO_3H\cdot\overset{6}{C_6H_2}Me(\overset{3}{N}H_2)\cdot\overset{5}{C_6H_2}Me(\overset{3'}{N}H_2)\cdot\overset{5'}{S}O_3H$, is obtained when barium ditolyldisulphonate is treated with concentrated nitric acid and the product reduced with ammonium sulphide; it crystallises from water, in which it is readily soluble, in colourless, well-defined needles. The *barium* salt, $C_{14}H_{14}N_2S_2O_6Ba + 4H_2O$, crystallises in yellowish needles, and is only sparingly soluble in boiling water. The *potassium* salt crystallises in plates, and is very readily soluble. When the barium salt is heated with lime, it seems to yield metatolidine.

Dicresol, $OH\cdot C_6H_3Me\cdot C_6H_3Me\cdot OH$, prepared from ditolyldisulphonic acid in the usual manner, crystallises in colourless needles, melts at 143°, and is readily soluble in alkalis.

Dicresoldisulphonic acid, $SO_3H\cdot C_6H_2Me(OH)\cdot C_6H_2Me(OH)\cdot SO_3H$, prepared by heating the tetrazo-derivative described above with a large quantity of water, is a crystalline substance very readily soluble in water, alcohol, and glacial acetic acid, but insoluble in ether and chloroform. The *potassium* salt, $C_{14}H_{12}S_2O_8K_2 + 3H_2O$, crystallises in colourless needles, and is very readily soluble in water. The *barium* salt crystallises in well-defined, rhombic plates with 8 mols. H_2O, and effloresces on exposure to the air.

Dihydrazineditolyldisulphonic acid,

$$SO_3H\cdot C_6H_2Me(N_2H_3)\cdot C_6H_2Me(N_2H_3)\cdot SO_3H,$$

obtained by reducing the tetrazo-compound with stannous chloride, is a yellowish, crystalline powder, very sparingly soluble in hot water; it turns yellowish-brown when heated at 100° and when exposed to the light, and is then very readily soluble in water, some decomposition having taken place with evolution of nitrogen. The *barium* salt, $C_{14}H_{16}N_4S_2O_6Ba$, seems to crystallise with 5 mols. H_2O, and is decomposed by boiling water with evolution of nitrogen.

The *diazo*-derivative, $SO_3H\cdot C_6H_2Me(NH_2)\cdot C_6H_2Me<\begin{matrix}N:N\\SO_3\end{matrix}>$ crystallises in yellowish needles, is only sparingly soluble in cold, and is decomposed by hot water with evolution of nitrogen.

Amidoditolyldisulphonic acid, $SO_3H\cdot C_6H_2Me(NH_2)\cdot C_6H_3Me\cdot SO_3H$, crystallises in slender needles, and is readily soluble in water, but only sparingly in dilute alcohol. The *barium* salt, $C_{14}H_{13}NS_2O_6Ba + 5H_2O$, crystallises in yellowish-red plates, and is only sparingly

soluble in water. The *potassium* salt is readily soluble, and crystallises in prisms.

Amidohydroxyditolyldisulphonic acid,

$$SO_3H\cdot C_6H_2Me(OH)\cdot C_6H_2Me(NH_2)\cdot SO_3H,$$

crystallises in almost colourless needles, and is very readily soluble in water, but insoluble in alcohol and ether. The *barium* salt, $C_{14}H_{13}NS_2O_7Ba + 4\frac{1}{2}H_2O$, crystallises in reddish plates, and is moderately easily soluble in water; the *potassium* salt and the *calcium* salt crystallise in prisms, and are readily soluble; the *silver* salt is crystalline.

Hydrazineamidoditolyldisulphonic acid,

$$SO_3H\cdot C_6H_2Me(N_2H_3)\cdot C_6H_2Me(NH_2)\cdot SO_3H,$$

prepared by reducing the corresponding diazo-compound with stannous chloride, is a yellowish, semi-crystalline powder, sparingly soluble in water. The *barium* salt, $C_{14}H_{15}N_3S_2O_6Ba + 6H_2O$, crystallises in golden needles, and decomposes when heated above 110°.

Hydrazotoluenedisulphonamide,

$$NH_2\cdot\overset{4}{S}O_2\cdot C_6H_3\overset{1}{M}e\cdot\overset{2}{N}H\cdot\overset{2}{N}H\cdot C_6H_3\overset{1}{M}e\cdot\overset{4}{S}O_2\cdot NH_2,$$

is obtained when orthonitrotoluneparasulphonamide is warmed with ammonia and zinc dust; it crystallises from hot water in long, colourless needles, and from glacial acetic acid and alcohol in prisms melting at 221—222°. It is almost insoluble in cold water and only sparingly soluble in ammonia, but readily in alcohol and potash; its alkaline solutions turn red on exposure to the air. The *potassium* derivative is deposited in almost colourless crystals when a solution of the acid in alcoholic potash is precipitated with ether and kept for some time in a closed vessel; it is stable in the air. The *diacetyl* derivative, $C_{18}H_{22}N_4S_2O_6$, prepared by boiling the hydrazo-compound with acetic anhydride, crystallises from alcohol in colourless needles, and melts at a very high temperature.

Azotoluenedisulphonamide is formed, together with tolidinedisulphonamide and amidotoluenesulphonamide (m. p. 175°), when the hydrazo-compound is heated with hydrochloric acid; it forms red crystals, and melts at 319·5°. The *potassium* derivative, $C_{14}H_{14}N_4S_2O_4K_2$, crystallises in intensely red, flat needles, and is decomposed by acids yielding azotoluenedisulphonamide.

Tolidinedisulphonamide,

$$NH_2\cdot SO_2\cdot C_6H_2Me(NH_2)\cdot C_6H_2Me(NH_2)\cdot SO_2\cdot NH_2,$$

crystallises from hot water in well-defined needles, melts at 304·5°, and is almost insoluble in cold water and only sparingly soluble in alcohol. When heated with concentrated hydrochloric acid at 150°, it is converted into the corresponding disulphonic acid. The *hydrochloride*, $C_{14}H_{18}N_4S_2O_4,2HCl + 2H_2O$, separates from water in lustrous needles, and from alcoholic ether as a colourless, crystalline powder melting at 284—285°: it is readily soluble in water and alcohol. The

sulphate, $C_{14}H_{18}N_4S_2O_4,H_2SO_4$, forms lustrous plates, and is more sparingly soluble in water than the hydrochloride. The *sodium* derivative, $C_{14}H_{16}N_4S_2O_4Na_2$, prepared by adding alcoholic ether to a solution of the amide in dilute soda, is a colourless, crystalline compound, very readily soluble in water. F. S. K.

Hydroxyaurin and Hydroxyaurincarboxylic Acids. By N. Caro (*Ber.*, **25**, 2671—2675).—The compounds described in this paper were prepared by the method previously described by the author (this vol., p. 855).

Hydroxyaurindicarboxylic acid, $O<\begin{matrix}C_6H_3\cdot OH\\ |\\ C[C_6H_3(OH)\cdot COOH]_2\end{matrix}$, separates from alcohol as a red, microcrystalline powder, decomposes at 140°, is easily soluble in alcohol, sparingly so in water, and soluble in ether. The barium, calcium, lead, aluminium, and iron salts are sparingly soluble or insoluble in water, and are dark-red to reddish-blue. The *calcium salt*, $C_{21}H_{12}O_8Cu$, is obtained by precipitating the ammoniacal solution of the free acid with calcium chloride.

Dihydroxyaurindicarboxylic acid is obtained by the condensation of methylenediresorcylic acid with phenol.

Trihydroxyaurindicarboxylic acid is obtained from methylenediresorcylic acid and resorcinol. It crystallises in microscopic leaflets, is soluble in hot water and alcohol, and insoluble in ether and benzene.

The condensation products of methylenedisalicylic acid or methylenediresorcylic acid with pyrogallol could not be obtained pure.

Methylenedigallic acid and phenols give bad yields, and the products are very difficult to purify owing to the ease with which they oxidise both in alkaline and aqueous solution.

Tetrahydroxyaurindicarboxylic acid, $O<\begin{matrix}C_6H_4\\ |\\ C[C_6H(OH)_3\cdot COOH]_2\end{matrix}$, prepared from methylenedigallic acid, is a reddish-violet powder which is soluble in alcohol, hot water, and alkalis, but insoluble in cold water.

Pentahydroxyaurindicarboxylic acid, $O<\begin{matrix}C_6H_3\cdot OH\\ |\\ C[C_6H(OH)_3\cdot COOH]_2\end{matrix}$, is obtained by the condensation of methylenedigallic acid and resorcinol in a solution of concentrated sulphuric acid (1 part) and acetic acid (1 part) at 5—7°.

The aurindicarboxylic acids give dyes with mordants; they are weaker and less beautiful than those from the tricarboxylic acids. The presence of resorcylic acid causes an orange shade, and of gallic acid a brown shade. Derivatives of methylenedigallic acid dye badly, owing to the ease with which they are oxidised. With regard to the absorption spectra, derivatives of salicylic acid exhibit an absorption between D and *b*; derivatives of resorcinol and resorcylic acid an absorption between *b* and F; mixed derivatives show dark bands in both positions.

Lastly, the author has made experiments to determine if an increase in the number of hydroxyl groups in aurin gives compounds capable of yielding colours with mordants.

The trihydroxyaurin described by Nencki and Schmid (*J. pr. Chem.*, **23**, 547) was prepared, and did not give dyes with mordants.

Hexahydroxyaurin (pyrogallaurin), $O<\begin{matrix}C_6H_2(OH)_2\\ |\\ C[C_6H_2(OH)_3]_2\end{matrix}$, is obtained by heating a mixture of pyrogallol (3 parts), formic acid (1 part), and zinc chloride (1 part) for 4 hours at 80°. It is a red, extremely hygroscopic powder, is easily soluble in alcohol and water, insoluble in ether, and oxidises very readily both in aqueous and alkaline solution. It yields dyes with mordants. E. C. R.

A New Synthesis of Diphenylene Oxide. By E. Täuber and E. Halberstadt (*Ber.*, **25**, 2745—2746).—The substance obtained by Täuber (Abstr., 1891, 570) by boiling the tetrazo-derivative of orthodiamidophenyl with water was compared with Graebe's diphenylene oxide and found to be identical. The yield of the oxide is about 70 per cent. of the diamine used. L. T. T.

Action of Aniline on Benzile. By M. Siegfeld (*Ber.*, **25**, 2600—2601).—Benzilemonanil was prepared by Voigt (Abstr., 1886, 887) by heating benzile with excess of aniline in a sealed tube at 200°; the benzile does not all react, but on heating for nine hours at 220°, benzanilide and benzaldehyde are produced.

Benziledianil, NPh:CPh·CPh:NPh, is obtained by heating a mixture of benzile (5 grams) and aniline with phosphoric anhydride for 6 hours in a sealed tube at 200°. A dark, solid mass and a thick, brown liquid are thus got; the latter, on crystallisation from alcohol, yields the dianil (2 grams) in brilliant, yellow leaflets which melt at 141—142°. It is soluble in chloroform, less so in benzene, and sparingly soluble in alcohol, ether, and light petroleum.

W. J. P.

Benzileoximes. By K. Auwers and M. Siegfeld (*Ber.*, **25**, 2597—2599).—*Benzileoximeanil*, OH·N:CPh·CPh:NPh, is prepared by heating benzile α- or γ-oxime with aniline in alcoholic acetic acid solution, and crystallises in colourless needles melting at 211—212°. The *acetyl derivative* is formed by the action of acetic anhydride on the preceding compound, and is deposited in small, yellow plates which melt at 135—136°. Attempts to obtain the same substance by the action of aniline on the acetyl derivatives of the oximes were unsuccessful.

Benzileoximeparatoluidil is prepared in a similar manner to the anil, which it closely resembles; in both cases the α-oxime reacts more readily than the γ-oxime; the same compound is also formed by the action of hydroxylamine hydrochloride on benzileditoluidil,

$$C_6H_4Me·N:CPh·CPh:N·C_6H_4Me,$$

at ordinary temperatures, and is deposited in colourless, acicular crystals which melt at 199—200°. The acetyl derivative crystallises in pale-yellow needles and melts at 120—121°. α-Benzile-

oxime combines with phenylhydrazine on heating in alcoholic acetic acid solution at 40° and forms *benzileoximehydrazone*,

$$OH\cdot N{:}CPh\cdot CPh{:}N\cdot NHPh,$$

which crystallises in colourless needles melting at 172—173°. The γ-oxime does not react with phenylhydrazine under these conditions. The *acetyl derivative* is formed by the action of acetic anhydride on the oximehydrazone at low temperatures; it crystallises in small, lustrous, yellow plates melting at 109°.

On treatment with hydroxylamine, benzilephenylhydrazone yields triphenylisotriazone, $NPh<\begin{matrix}N{:}CPh\\ |\\ N{:}CPh\end{matrix}$, which melts at 120—121°.

J. B. T.

Acids from the Dicyanhydrin of Benzoylacetone. By M. Carlson (*Ber.*, **25**, 2728—2731).—The *dicyanhydrin*,

$$CH_2[CPh(CN)\cdot OH]_2,$$

obtained by mixing an alcoholic solution of benzoylacetone with potassium cyanide, and gradually adding hydrochloric acid of sp. gr. 1·19, yields, on boiling with dilute hydrochloric acid, two isomeric monobasic lactonic acids, $C_{12}H_{12}O_5$, melting at 174—175° and 163° respectively. The same *methylphenyldihydroxyglutaric acid*, $C_{12}H_{14}O_6$, of melting point 168°, is produced on treating the potassium salts of either of the lactonic acids with the necessary quantity of hydrochloric acid. On heating the dihydroxy-acid at 170—175°, it is converted into a mixture of the two lactonic acids. A. R. L.

Naphthylene Dihydrosulphide and Dithiocyanate. By L. Braun and R. Ebert (*Ber.*, **25**, 2735—2739; compare Abstr., 1891, 460).—Naphthylene dihydrosulphide [$(SH)_2 = 2:3'$] (*loc. cit.*) is obtained in most favourable yield (11·6 per cent. of the theoretical) by heating the corresponding sulphonic chloride with zinc dust and acetic acid over a free flame. On extracting the dihydrosulphide with alcohol, the residue was found to be insoluble in ether, and on further extraction with benzene, it was obtained free from chlorine; it then melted at 270°, and appeared to be a naphthylene bisulphide. When the above-mentioned sulphonic chloride is heated with hydriodic acid and phosphorus for 10 hours, 2·6 per cent. of the theoretical amount of dihydrosulphide was isolated, whilst only naphthalene was obtained on continuing the heating for 24 hours. The pure dihydrosulphide forms colourless, lustrous scales, melts at 177—178°, and has a faint characteristic odour. A dithiocyanate, resembling that already described (*loc. cit.*), but melting at 96°, was obtained by treating the lead compound of the dihydrosulphide, suspended in alcohol, with cyanogen chloride or bromide.

1 : 4'-*Naphthalene dihydrosulphide* passes over in an amount reaching 80 per cent. of the theoretical when the corresponding sulphonic chloride is heated on the water-bath with zinc dust and acetic acid in a current of steam; it forms lustrous, silvery leaflets which become yellowish on keeping, and melts at 103°. A. R. L.

Orthodiamines. By O. Fischer (*Ber.*, **25**, 2826—2846; see also Abstr., 1891, pp. 434, 746, and 1109).—The compounds obtained by the condensation of mono-substituted orthodiamines with aldehydes may be either benzylidene compounds or dihydroimidazoles, and have the constitution $NHR'\cdot C_6H_4\cdot N{:}CHR'$ or $C_6H_4{<}\overset{NH}{NR'}{>}CHR'$. Thus, when boiled with acids they are resolved into their components, and, therefore, behave like benzylidene compounds, and it is probable that such benzylidene compounds on oxidation would yield anhydro-bases. However, ethylamidophenylnaphthylamine, $NHPh\cdot C_{10}H_6\cdot NHEt$, when treated with benzaldehyde, yields a condensation product which is resolved into its components by acids, and cannot be a benzylidene compound and must be regarded as a dihydroimidazole. The author is of opinion that the condensation products from mono-substituted orthodiamines are also dihydroimidazoles.

When orthophenylnaphthylenediamine and benzaldehyde in molecular proportion, mixed with a few drops of absolute alcohol, are warmed at 50—70° for 15—20 minutes, a yellow, crystalline compound is obtained of the formula $NHPh\cdot C_{10}H_6\cdot N{:}CHPh$ or

$$C_{10}H_6{<}\overset{NH}{NPh}{>}CHPh.$$

It crystallises from alcohol or benzene in sulphur-yellow prisms, melts at 138°, is insoluble in water, easily soluble in alcohol, benzene, chloroform, and ether, and by boiling with acids is resolved into benzaldehyde and phenylnaphthylenediamine.

Phenylbenzenyl-αβ-naphthylenediamine, $C_{10}H_6{<}\overset{\quad N}{NPh}{>}CPh$, is obtained by warming the mixture of benzaldehyde and orthophenylnaphthylenediamine for 4—5 hours on the water-bath. It is also obtained by repeated crystallisation of the preceding compound from boiling alcohol. It crystallises in white needles, melts at 142—143°, is not decomposed by boiling with acids, and is somewhat soluble in hot water, sparingly in alcohol and benzene, and easily so in a mixture of the last solvents. The alcoholic solution has a beautiful blue fluorescence. The *hydrochloride* is a crystalline powder, sparingly soluble in water. The *platinochloride* crystallises in yellow leaflets, and is sparingly soluble in alcohol. The *sulphate* crystallises in slender, pale rose-coloured needles.

Salicylaldehyde and orthophenylnapthylenediamine yield a brick-red condensation product which crystallises in red, interlacing needles, melts at 139°, is easily soluble in alcohol, benzene, and ether, and is resolved into its components when boiled with acids.

Phenylhydroxybenzenylnaphthylenediamine is obtained by repeated crystallisation of the preceding red compound; it forms yellowish-white leaflets, melts at 175—176°, and is easily soluble in alcohol, ether, and benzene. The *hydrochloride* is very sparingly soluble in water, and crystallises from alcohol in slender, white needles.

The three nitrobenzaldehydes and orthophenylnaphthylenediamine yield similar condensation products to the above. Brown or

red compounds are first formed and by repeated crystallisation are converted into bright-yellow anhydro-bases.

Phenylorthonitrobenzenylnaphthylenediamine crystallises from alcohol in lemon-yellow, silky needles, melts at 242°, is easily soluble in benzene, and somewhat sparingly so in alcohol. The alcoholic solution has a pale greenish-yellow fluorescence. The *platinochloride* crystallises from alcohol in beautiful golden leaflets.

Phenylparanitrobenzenylnaphthy'enediamine crystallises in golden needles, melts at 238°, and is sparingly soluble in alcohol, more easily so in benzene.

Phenylmetanitrobenzenylnaphthylenediamine crystallises from alcohol in yellow tablets and melts at 209°.

Phenylisopropylbenzenylnaphthylenediamine is obtained by repeated crystallisation of the brownish-red condensation product from cuminaldehyde and orthophenylnaphthylenediamine. It crystallises in six-sided leaflets, melts at 136°, and is easily soluble in alcohol, benzene, and ether.

Paratolylorthonaphthylenediamine was prepared by adding paratolyl-β-naphthylamine to an alcoholic solution of diazobenzene chloride and then reducing the azo-derivative with stannous chloride and acetic acid. It crystallises from alcohol or light petroleum in needles or plates, is obtained in very beautiful crystals from methyl alcohol, melts at 128°, and turns violet on exposure to light.

A *thio-compound* of the formula $C_{10}H_6<\overset{NH}{N(C_7H_7)}>C{:}S$ or

$$C_{10}H_6<\overset{\qquad N}{N(C_7H_7)}>C{\cdot}SH$$

is obtained by boiling the preceding diamine with carbon bisulphide for four hours in a reflux apparatus. It crystallises from acetic acid in beautiful pale-yellow needles, melts at 307°, is insoluble in benzene, light petroleum, and chloroform, very sparingly soluble in alcohol, and yields a very unstable sodium salt which crystallises in beautiful lustrous, white leaflets.

The *anhydro-base*, $C_{10}H_6<\overset{\qquad N}{N(C_7H_7)}>CPh$, is obtained by warming molecular proportions of paratolylorthonaphthylenediamine and benzaldehyde mixed with a little absolute alcohol on the water-bath for half an hour. It crystallises from alcohol in beautiful white prisms, melts at 155°, is easily soluble in benzene, petroleum, and ether, more sparingly so in alcohol, and is not decomposed by boiling with dilute sulphuric acid.

With metanitrobenzaldehyde, the above diamine yields a similar anhydro-base, which crystallises from alcohol in aggregates of yellowish-brown needles, and melts at 197°; it is insoluble in water, but soluble in alcohol and benzene, more sparingly so in ether and light petroleum.

Salicylaldehyde and paratolylnaphthylenediamine yield a red crystalline compound which, on recrystallisation, is converted into the *anhydro-base*. The latter crystallises from alcohol in yellowish-green leaflets, melts at 217°, is soluble in benzene, ether, and light petroleum,

and insoluble in water. It dissolves in concentrated sulphuric acid with a blue coloration, which on the addition of water turns red and finally disappears.

Tolyldiphenylnaphthodihydroquinoxaline, $C_{10}H_6<\overset{N=CPh}{N(C_7H_7)}>CHPh$, is prepared by heating benzoïn and paratolylnaphthylenediamine, in molecular proportion, in a sealed tube at 210° for two hours. It crystallises from absolute alcohol in lustrous, yellow leaflets, melts at 175°, is insoluble in water, very sparingly soluble in alcohol, easily so in ether, benzene, and petroleum; with mineral acids, it gives dark-red salts which are decomposed by water.

The *azonium base*, $C_{10}H_6<\overset{N=CPh}{N(OH)(C_7H_7)}>CPh$, is obtained by oxidising the preceding compound in alcoholic solution with ferric chloride. It crystallises from absolute alcohol in yellowish-green prisms, and melts at 194°. The solution in ether, benzene, petroleum, or absolute alcohol exhibits a beautiful yellowish-green fluorescence. It dissolves in concentrated sulphuric acid with a dark reddish-violet coloration, which, on the addition of water, successively turns bright red and then pure yellow, with a strong fluorescence. The *iron salt*, $C_{31}H_{23}N_2Cl,FeCl_3$, is soluble in water, insoluble in alcohol, and is decomposed by boiling with sodium carbonate. The *hydrochloride* crystallises from dilute alcohol in lustrous, broad, yellow plates, containing 1 mol. of alcohol, and is sparingly soluble in water. The *hydrobromide* crystallises from dilute alcohol in lustrous, yellow leaflets. The *nitrate* crystallises from dilute alcohol in yellow needles, and is sparingly soluble in water, easily so in alcohol. The *sulphate* crystallises in yellow leaflets The azonium base is also obtained by heating dibenzoyl and tolylnaphthylenediamine, in molecular proportion, in concentrated alcoholic solution until a sample no longer gives a red coloration with ferric chloride. The yield is quantitative.

When orthophenylenediamine hydrochloride is heated with methyl alcohol (4 mols.) for three hours at 180°, and the product treated with sodium hydroxide, distilled with steam, and the distillate extracted with ether, a dark-coloured, viscid oil is obtained which cannot be purified by fractional distillation. If this oil is treated with acetic anhydride and the acetyl compounds mixed with dilute soda and distilled with steam, a yellow oil passes over, and long, slender needles separate from the aqueous liquid on cooling. The needles are methylphenylenethenylamidine. The oil, on fractional distillation, yields a small quantity of tetramethylorthophenylenediamine, boiling at 215—218°.

Tetramethylorthophenylenediamine is easily obtained by heating orthophenylenediamine with methyl iodide and methyl alcohol, at 180°, for 10 hours. It boils at 215—218°, under a pressure of 735 mm., is insoluble in sodium hydroxide, sparingly soluble in water, easily so in most organic solvents; it is extremely sensitive to light and air, and soon turns black on exposure with partial decomposition. The *hydrochloride* crystallises in small, colourless prisms, melts at 180°, is soluble in water in all proportions, less soluble in absolute alcohol, and quickly turns red on exposure to air. The *platinochloride* crystallises in stout, reddish-brown crystals.

Methylphenylenethenylamidine, $C_6H_4<^{NMe}_{\ \ N}>CMe$, is also obtained by heating phenylethenylamidine with methyl iodide in a sealed tube at 100°. It distils at 290°, solidifies in the receiver in radiating needles, and melts at 112°. The *hydrochloride* is obtained in beautiful crystals by adding alcoholic hydrogen chloride to an alcoholic solution of the base, and is extremely soluble in water. The *platinochloride* crystallises in beautiful brown needles. The *aurochloride* crystallises in lustrous, golden needles. The *methiodide* is obtained by heating the base with methyl iodide in a sealed tube at 100°; it crystallises in large prisms, and melts at 254°.

Methylorthophenylenediamine is obtained by methylating orthonitraniline, and, after purifying the methylnitraniline by steam distillation, reducing it with tin and hydrochloric acid. The product is then purified by steam distillation. It boils at 245—248° under 736 mm. pressure, and quickly darkens on exposure to air. The *hydrochloride* separates in well formed rhombic crystals, melts at 191°, and is sensitive to light and air. When the base is boiled with acetic anhydride, it is converted into ethenylmethylphenyleneamidine. When warmed with benzaldehyde, it yields a compound of the formula

$$C_6H_4<^{NMe}_{\ \ N}>CPh.$$

This crystallises from dilute alcohol in slender, colourless needles, and melts at 170—171°. With orthonitrobenzaldehyde, the diamine yields the benzylidene derivative, $NHMe{\cdot}C_6H_4{\cdot}N{:}CH{\cdot}C_6H_4{\cdot}NO_2$. This crystallises from ether in lustrous, yellow leaflets, and is resolved into its components when boiled with acids. With salicyldehyde, the diamine yields a yellow, crystalline compound, which melts at 110—111°, and is resolved into its components when boiled with acids. By repeated crystallisation from alcohol, it is converted into the anhydro-base. The latter is colourless, and melts at 164—165°.

Difurylquinoxaline, $C_6H_4<^{N=C{\cdot}C_4OH_3}_{N=C{\cdot}C_4OH_3}$, is obtained by heating furoïn and orthophenylenediamine in a sealed tube, at 150°, for four hours. It crystallises from alcohol in pale-yellow needles, melts at 134°, and is easily soluble in benzene, ether, and chloroform, but only very sparingly in light petroleum. The solution of the impure product in ether or benzene exhibits a violet-blue fluorescence. An attempt to prepare difuryldihydroquinoxaline by filling the tube with carbonic anhydride was unsuccessful.

Difurylnaphthoquinoxaline is obtained by heating furoïn and $\alpha\beta$-naphthylenediamine at 200°. A small quantity of the dihydro-compound is also obtained, and imparts a greenish-blue fluorescence to the solutions of the crude product. It crystallises from alcohol in golden needles, and melts at 147°.

Difuryltoluquinoxaline, prepared from 1 : 3 : 4-toluylenediamine in the same way, crystallises from alcohol in yellow needles, melts at 176°, and is easily soluble in ether and benzene, sparingly in light petroleum.

Phenyldifurylnaphthodihydroquinoxaline, $C_{26}H_{18}N_2O_2$, is obtained from furoïn and phenylnaphthylenediamine; it crystallises from alcohol

in yellow needles, and melts at 176°. The solution in ether or benzene exhibits a beautiful yellowish-green fluorescence. The *hydrochloride* crystallises in claret coloured needles. When oxidised in alcoholic solution with ferric chloride, it yields the *azonium base*, $C_{10}H_6<\begin{matrix}N \text{ ——— } C\cdot C_4OH_3\\ NPh(OH)\cdot C\cdot C_4OH_3\end{matrix}$; this crystallises from alcohol in beautiful transparent, yellowish-green prisms, melts at 160°, and is easily soluble in ether, benzene, and chloroform, sparingly in light petroleum.

Tolyldifurylnaphthodihydroquinoxaline is obtained from furoïn and paratolylnaphthylenediamine. It crystallises from alcohol in lustrous, yellow needles, and melts at 186°. The solution in benzene or ether shows a beautiful greenish-yellow fluorescence. The alcoholic solutions of the salts are intensely dark-red.

In the preparation of the preceding compound, *benzeneazo-β-tolylnaphthylamine* and *tolylnaphthylenediamine* were prepared. The former crystallises from acetic acid in lustrous, dark-red leaflets, and melts at 156°. The latter crystallises from petroleum in aggregates of lustrous, white needles, and melts at 146—147°. E. C. R.

Formation of Indulines. By O. Fischer and E. Hepp (*Ber.*, **25**, 2731—2734).—Whereas the formation of indulines from anilidoquinoneimides is readily explained, that of the quinoneimides from amidoazo-compounds is obscure. Assigning a hydrazone formula to amidoazobenzene (Goldschmidt), the formation of anilidoquinonediimide is represented by the following intramolecular change:—$NH{:}C_6H_4{:}N\cdot NHPh = NH{:}C_6H_5(NH)\cdot NHPh$. When benzeneazo-α-phenylnaphthylamine is heated at 130° with 80 per cent. acetic acid, a small quantity of anilidonaphthaquinoneanil is formed; also, when benzeneazo-α-naphthol is boiled for 8—10 hours with glacial acetic acid, a certain quantity of anilidonaphthaquinone (Plimpton, Trans., 1880, 639) is obtained. The primary product in the last case is, doubtless, the anilidoquinoneimide, $O{:}C_{10}H_5(NH)\cdot NHPh$ [1 : 3 : 4]. Besides the quinone derivative and unaltered benzeneazo-α-naphthol, an amorphous compound, $C_{24}H_{19}N_3O_2$, melting at 233° was also isolated; this, when boiled with alcoholic sulphuric acid, gives a compound which is, perhaps, a carbazole derivative. A. R. L.

Action of Aniline on β-Naphtholcarboxylic Acid. By M. Schöpff (*Ber.*, **25**, 2740—2745).—When 2 : 3-naphtholcarboxylic acid (m. p. 216°) is heated with an excess of aniline in a reflux apparatus for 8—10 hours, the product mixed with dilute hydrochloric acid, and the excess of aniline boiled off, the solid portion, after extracting with hot alcohol, consists of *β-hydroxynaphthoic anilide*, $OH\cdot C_{10}H_6\cdot CONHPh$, which crystallises from glacial acetic acid in nacreous leaflets, but is insoluble in most solvents, and melts at 243—244°. On adding water to the alcoholic extract, a precipitate is produced, which is collected, and, on treatment with sodium carbonate solution, leaves *β-anilidonaphthoic anilide*, $NHPh\cdot C_{10}H_6\cdot CONHPh$; this crystallises from glacial acetic acid in greenish tables, and melts at 168—169·5°. *β-Anilidonaphthoic acid*, $NHPh\cdot C_{10}H_6,COOH$, is contained in the sodium carbonate solution together with a large quantity of unaltered naph-

tholcarboxylic acid, and is separated from the latter by fractional precipitation with an acid; it crystallises from alcohol in golden-yellow needles, and melts at 235—237°; the *sodium* salt contains $1\frac{1}{2}$ mols. H_2O. When the acid is heated with zinc chloride at 200—220°, a compound is obtained, dissolving in most solvents with an intensely green fluorescence; it is, probably, *phenonaphthacridone*, $C_{10}H_6<\begin{matrix}NH\\CO\end{matrix}>C_6H_4$ (compare this vol., p. 1223), and is being further investigated. A. R. L.

1 : 2-Dicyanonaphthalene and 1 : 2-Naphthalenedicarboxylic Acid. By P. T. Cleve (*Ber.*, **25**, 2475—2479).—1 : 2-*Dicyanonaphthalene* is prepared by heating potassium 1 : 2-chlorosulphonate with dehydrated potassium ferrocyanide in a rapid current of carbonic anhydride. The yield amounts to about 12 per cent. of the potassium salt employed. It crystallises from benzene in flexible, asbestos-like needles, sublimes in long, lustrous, colourless needles, melts at 190°, and dissolves sparingly in alcohol, more readily in chloroform, benzene, acetic acid, or amyl alcohol. By prolonged heating with hydroxylamine, it is converted into the *dioximimide* of naphthalenedicarboxylic acid, $C_{10}H_6<\begin{matrix}C(N\cdot OH)\\C(N\cdot OH)\end{matrix}>NH$, a yellowish, crystalline powder, which melts at 260°, is very sparingly soluble in alcohol, benzene, or chloroform, and on treatment with acetic anhydride, yields a crystalline *diacetyl* derivative, $C_{10}H_6{:}C_2N_2(OAc)_2{:}NH$, melting at 213°.

1 : 2-*Naphthalenedicarboxylic acid*, $C_{10}H_6(COOH)_2$, obtained by the hydrolysis of the dicyano-derivative, is a heavy, crystalline powder, sparingly soluble in cold, but tolerably soluble in hot, water. It melts at 175°, undergoing conversion into the *anhydride*, which sublimes in long, colourless needles, melts at 165°, and dissolves readily in benzene, but is almost insoluble in water. The anhydride gradually regenerates the acid on boiling with water, and in many respects resembles phthalic anhydride, giving phthaleïns, for example, when heated with phenol or resorcinol and zinc chloride. *Potassium naphthalenedicarboxylate* is very soluble, and crystallises from a syrupy solution in tabular forms. Acetic acid precipitates from its aqueous solution a sparingly soluble, crystalline salt of the composition $C_{10}H_6(COOH)_2 + COOH\cdot C_{10}H_6\cdot COOK + 4H_2O$. The *sodium* salt is also very soluble, and, from its solution, acetic acid precipitates a sparingly soluble, crystalline, acid sodium salt of analogous composition. The *silver*, *magnesium*, *calcium* with $1H_2O$, *barium*, *barium hydrogen* with $8H_2O$, and *copper* salts are described. The *amide*, $C_{10}H_6(CONH_2)_2$, crystallises in small, rhombic forms, dissolves sparingly in water but readily in aqueous soda, and melts at 265°, evolving ammonia, and undergoing conversion into the *imide*, $C_{10}H_6{:}C_2O_2{:}NH$, which sublimes in long needles, melts at 224°, and is sparingly soluble in benzene and chloroform. W. J. P.

Chloronaphthalenesulphonic Acids. By P. T. Cleve (*Ber.*, **25**, 2479—2484).—After summarising the work of himself and his pupils on the chloronaphthalenesulphonic acids, the author describes a series of salts of the following acids.

1 : 2′-α-Chloronaphthalenesulphonic acid (compare Armstrong and Wynne, Proc., 1889, 49), prepared from 1 : 2′-α-amidonaphthalenesulphonic acid (Abstr., 1889, 155) by Sandmeyer's method, is readily soluble, and crystallises in aggregates of needles. The *potassium*, *barium* with $3H_2O$, and *silver* salts are described. The *ethyl* salt, $C_{10}H_6Cl\cdot SO_3Et$, crystallises from alcohol in large, flat plates, and melts at 90°. The chloride melts at 94°, and the amide at 181° (185—186° according to Armstrong and Wynne).

2 : 4′-β-Chloronaphthalenesulphonic acid, obtained from 2 : 4′-β-amidonaphthalenesulphonic acid (Dahl's acid) by Sandmeyer's method (compare Armstrong, *Brit. Assoc. Rep.*, 1888; Armstrong and Wynne, Proc., 1889, 498), crystallises from a concentrated solution in tolerably large, tabular crystals. The *potassium* with H_2O, sodium with H_2O, *calcium* with $2H_2O$, *barium* with $2H_2O$, *zinc* with $6H_2O$, *copper* with $7H_2O$, and *silver* salts are described. The *ethyl* salt, $C_{10}H_6Cl\cdot SO_3Et$, crystallises from alcohol in large and somewhat sparingly soluble prisms, and melts at 114·5°. The chloride melts at 69°, the *amide* crystallises in silvery scales melting at 214°.

2 : 2′-Chloronaphthalenesulphonic acid, prepared from 2 : 2′-amidonaphthalenesulphonic acid (F-, or Bayer and Duisberg's acid) by Sandmeyer's method (compare Armstrong, *loc. cit.*; Armstrong and Wynne, Proc., 1889, 49), crystallises with $4H_2O$ from a concentrated solution in large, tabular forms, which melt at 68°; the anhydrous acid melts at 118°. The *potassium* with H_2O, *sodium*, *magnesium* with $8H_2O$, *calcium* with $8H_2O$, *barium* with H_2O, *lead* with $2H_2O$, *zinc* with $8H_2O$, *copper* with $8H_2O$, and *silver* salts are described. The *methyl* salt, $C_{10}H_6Cl\cdot SO_3Me$, is obtained from alcoholic solution in well-formed crystals, and melts at 89°; the *ethyl* salt melts at 65°. The chloride melts at 86·5°, and the amide at 176°. W. J. P.

1 : 2 : 2′-α-Nitrochloronaphthalenesulphonic Acid. By P. T. Cleve (*Ber.*, **25**, 2485—2490).—The chloride of 1 : 2 : 2′-*α-nitrochloronaphthalenesulphonic acid* [$NO_2 : Cl : SO_3H = 1 : 2 : 2'$] is obtained by introducing finely-powdered 2 : 2′-chloronaphthalenesulphonic chloride into cooled nitric acid of sp. gr. 1·5. Accompanying the 1 : 2 : 2′-derivative is a small quantity of a second chloride, which melts at 145°, but has not been further examined. The *potassium*, *sodium*, *calcium* with $5H_2O$, *barium* with $3H_2O$, and *silver* salts of 1 : 2 : 2′-nitrochloronaphthalenesulphonic acid are described. The *ethyl* salt, $NO_2\cdot C_{10}H_5Cl\cdot SO_3Et$, crystallises in almost colourless, microscopic needles, melts at 184°, and is very sparingly soluble in alcohol or chloroform. The *chloride* forms small, bright yellow needles, melts at 219°, and dissolves very sparingly in acetic acid or chloroform; the *amide* crystallises in slender, pale yellow, asbestos-like needles, and melts at 247°. On treatment with hydriodic acid, the chloride is converted into a sparingly soluble substance of the composition $(C_{10}H_5Cl\cdot NO_2)_2S_2$, melting at 217°, and the amide into 1 : 2′-α-amidonaphthalenesulphonamide (Abstr., 1889, 155). On distillation with phosphorus pentachloride, the chloride yields a trichloronaphthalene which crystallises in small, granular forms, melts at 75·5°, dissolves readily in alcohol

and acetic acid, and is regarded as identical with Alén's trichloronaphthalene of like melting point.

1 : 2 : 2′-*α-Amidochloronaphthalenesulphonic acid*, obtained from the potassium salt of the nitro-acid by boiling with ferrous sulphate and aqueous potash, crystallises in microscopic needles, and is tolerably soluble in boiling water. It is converted by Sandmeyer's method into 1 : 2 : 2′-dichloronaphthalenesulphonic acid, and of this acid the *potassium*, *sodium* with H_2O, *silver* with H_2O, *magnesium* with $9H_2O$, *calcium* with $2H_2O$, and *barium* with $3H_2O$ salts are described. The *ethyl* salt, $C_{10}H_5Cl_2{\cdot}SO_3Et$, crystallises from alcohol in small needles, and melts at 123°. The chloride melts at 124°, and the amide at 227° (compare Armstrong and Wynne, Proc., 1889, 49). On hydrolysis, the potassium salt yields 1 : 2-dichloronaphthalene.

W. J. P.

3′-Methyl-α-naphthindole. By A. Reissert and A. Junghahn (*Ber.*, **25**, 2698—2700).—*3′-Methyl-α-naphthindole*, $C_{10}H_6{<}\begin{matrix}NH\\CMe\end{matrix}{>}CH$, is prepared by heating α-naphthylamine (2 mols.) with chloracetone (1 mol.) on the water-bath for four hours, and, after extracting the α-naphthylamine hydrochloride from the product with hot water, collecting the residue, drying, powdering, and distilling it. The solid distillate is repeatedly recrystallised from alcohol, when it forms lustrous, silvery plates; it is readily soluble in acetic acid, benzene, and hot alcohol, melts at 198°, and decomposes with the formation of a blue liquid on boiling with concentrated hydrochloric acid; a pine splinter moistened with hydrochloric acid is coloured blue by its solutions. The *acetyl* derivative, $C_{13}H_{10}NAc$, formed by boiling the compound with acetic anhydride, crystallises from alcohol in faint, reddish needles, and melts at 228°. An isomeric methyl-α-naphthindole is described by Schlieper (Abstr., 1887, 964).

A. R. L.

Menthene. By F. A. Sieker and E. Kremers (*Amer. Chem. J.*, **14**, 291—293).—Fifty grams of menthol and 100 grams of potassium hydrogen sulphate are heated in a reflux apparatus for 6—8 hours at a temperature of 180—200°. The product is steam distilled and the resulting oil fractionated, yielding menthene, boiling at 167—168°, and unchanged menthol. Menthene thus obtained is a colourless, mobile liquid, of a peculiar (not menthol-like) odour. Its specific gravity at 20° is 0·814. It is dextrorotatory, $[\alpha]_D = +26{\cdot}40°$, although obtained from lævorotatory menthol.

The nitrosite reaction, as applied by Wallach to terpinene, gave no result with menthene. A *nitrosochloride*, $C_{10}H_{18}NOCl$, was obtained as a white, crystalline powder as follows:—15 c.c. of menthene was dissolved in 15 c.c. of glacial acetic acid and 11 c.c. of ethyl nitrite, and cooled; 6 c.c. of hydrochloric acid in an equal volume of glacial acetic acid was then added gradually. About 4 grams of white, crystalline nitrosochloride was obtained. It was purified by dissolving in the smallest possible quantity of chloroform, filtering, and precipitating with alcohol. It melts at 113° without decomposition, but decomposes at about 152°. It is readily soluble in chloroform, less so in ether, and but sparingly soluble in alcohol.

Menthene nitrosochloride, when heated with benzylamine, yields a crystalline substance, very likely a nitrolamine base. The study of menthene and its derivatives will be continued. W. T.

Cantharene. By J. Piccard (*Ber.*, **25**, 2453).—The author quotes from his previous papers to show that he has long anticipated Baeyer's conclusion (this vol., p. 1183) that cantharene is probably a dihydro-orthoxylene, of the nature of a terpene. C. F. B.

Cineolic Acid. By G. Elkeles (*Annalen*, **271**, 20—27).—*Cineolic piperidide*, $COOH\cdot C_8H_{14}O\cdot CO\cdot C_5NH_{10}$, is obtained in colourless crystals when a dry ethereal solution of cineolic anhydride is treated with anhydrous piperidine in molecular proportion, and then evaporated in a dry atmosphere; it melts at 151—152°, and forms a sparingly soluble *silver* salt of the composition $COOAg\cdot C_8H_{14}\cdot OCO\cdot C_5NH_{10}$. The *allylamide*, $COOH\cdot C_8H_{14}O\cdot CO\cdot NH\cdot C_3H_5$, prepared in like manner, separates from a mixture of ether and methyl alcohol in crystals, and melts at 126°. The *diethylamide*, $COOH\cdot C_8H_{14}O\cdot CO\cdot NEt_2$, is a colourless, crystalline compound, melting at 162—163°. The *anilide* is a syrup, but when treated with anhydrous ammonia in ethereal solution, it is converted into a solid, colourless, hygroscopic *ammonium* salt, from which the *silver* salt, $COOAg\cdot C_8H_{14}O\cdot CO\cdot NHPh$, can be prepared; the last-named compound reacts with methyl iodide, yielding the *methyl* salt, $COOMe\cdot C_8H_{14}O\cdot CO\cdot NHPh$, a crystalline compound melting at 78—79°. The *paratoluidide*,

$$COOH\cdot C_8H_{14}O\cdot CO\cdot NH\cdot C_6H_4Me,$$

separates from a mixture of ether and methyl alcohol in crystals melting at 125—126°; its *silver* salt, $COOAg\cdot C_8H_{14}O\cdot CO\cdot NH\cdot C_6H_4Me$, is a colourless, amorphous compound. The *phenylhydrazide*,

$$COOH\cdot C_8H_{14}O\cdot CO\cdot N_2H_2Ph,$$

crystallises in needles, and melts at 110°. The *amide*,

$$COOH\cdot C_8H_{14}O\cdot CO\cdot NH_2,$$

is crystalline.

When the paratoluidide described above is submitted to dry distillation, it is decomposed into toluidine, carbonic oxide, carbonic anhydride, and the compound of the composition $C_8H_{14}O$, previously described by Wallach (Abstr., 1890, 1314); the last-named substance is slowly converted into metaxylene when boiled with dilute sulphuric acid, more quickly when heated with the dilute acid at 150°.

The monocarboxylic acid, $C_8H_{15}O\cdot COOH$, obtained by heating cineolic acid (compare Wallach, *loc. cit.*) can be converted into its methyl salt by treating it with hydrogen chloride in methyl alcoholic solution; this compound boils at 125°, under a pressure of 13 mm., and has the composition $C_{10}H_{18}O_3$. F. S. K.

Kuromoji Oil. By W. Kwasnik (*Arch. Pharm.*, **230**, 265—286).—The volatile oil is obtained from the "Kuromoji" (*Lindera sericea*, Blume), a tree growing in all the uplands of Japan, and appears to be derived from both the wood and the leaves of the

plant. It was only introduced into Europe in 1888, and has not hitherto been chemically investigated. The material examined was obtained from Schimmel, of Leipsic. It is clear, dark-yellow in colour, has a strong aromatic odour, and a sp. gr. of 0·901 at 18°, 0·896 at 20°. It is very feebly lævorotatory, the small amount of the rotation being due to the presence of nearly equal quantities of dextro- and lævo-rotatory constituents. It forms a clear solution in alcohol, ether, benzene, light petroleum, acetic acid, and fatty oils. In chloroform and carbon bisulphide, it forms a cloudy solution, but the solution in chloroform is rendered clear by the addition of a small quantity of alcohol. It contains neither nitrogen nor sulphur, and is neutral to litmus. It is attacked by metallic potassium in the cold, gives a dark, somewhat violet coloration with ferric chloride, and decolorises potassium permanganate in the cold. Its constituents were partially separated by repeated fractional distillation, and isolated and identified by chemical means. The oil was thus found to contain: (1) dextrorotatory limonene, $C_{10}H_{16}$; (2) dipentene, $C_{10}H_{16}$; (3) terpineole, $C_{10}H_{18}O$; and (4) carvol, $C_{10}H_{44}O$, all of which are nearly related to one another, and for the most part interconvertible.

C. F. B.

Camphene and Camphoric Acid. By O. Wallach (*Ber.*, **25**, 2444).—The author declines to again correct the misstatements in a recently published paper of Brühl's (this vol., p. 1240).

Hydrazones of Camphoric Acid. By E. M. Chaplin (*Ber.*, **25**, 2565—2568).—Campherylphenylhydrazine is prepared by heating phenylhydrazine and camphoric anhydride in molecular proportion for several hours at 150°, and is identical with the substance obtained by Haller from methyl camphorate and phenylhydrazine; on treatment with alkalis and subsequent acidification, an acid is formed; it has the formula $C_{16}H_{24}N_2O_4$, and is deposited from chloroform in colourless crystals melting at 91—92°; it readily reduces alkaline copper solution.

Acetylcampherylphenylhydrazine $C_{16}H_{19}N_2O_2Ac$, is obtained on heating the hydrazine with 2·5 parts of acetic anhydride, and crystallises from alcohol in prisms which melt at 107°. The *nitro*-derivative, $C_{16}H_{19}N_3O_4$, is prepared by the action of nitrous acid on the hydrazine in acetic acid solution at 0° and crystallises from alcohol in pale-yellow needles melting at 157°. The *dinitro*-derivative, $C_{16}H_{18}N_4O_6$, is formed by the action of nitrous acid on the hydrazine at higher temperatures; it resembles the preceding compound in appearance, is sparingly soluble in alcohol, and melts at 192°.

Paratolylhydrazinecamphoric acid, $C_6H_4Me\cdot N_2H_2\cdot CO\cdot C_9H_{14}\cdot COOH$, is prepared by heating paratolylhydrazine with camphoric anhydride at 130°; it crystallises from alcohol in prismatic plates and melts at 193°; when heated at 200°, it yields *campherylparatolylhydrazine*, which is also formed by heating camphoric acid and paratolylhydrazine at 150°; this closely resembles the phenyl derivative in properties, and crystallises in colourless needles melting at 146°.

J. B. T.

Spontaneous Conversion of Isoprene into Caoutchouc. By W. A. Tilden (*Chem. News*, **65**, 265).—The author observed that some isoprene, prepared from turpentine, and stored in bottles, changed spontaneously into india-rubber, the liquid being at the same time acid, and still containing some unchanged isoprene. As an explanation of the phenomenon, it is suggested that the change may be due to the presence of a little acetic or formic acid produced by atmospheric oxidation. D. A. L.

Digitalin. By H. Kiliani (*Arch. Pharm.*, **230**, 250—261; compare also Abstr., 1890, 996; 1891, 576; and this vol., 501).—The leaves and seeds of *Digitalis purpurea* contain *digitonin*, a crystalline inactive glucoside resembling saponin, the crystalline substance *digitoxin*, and two amorphous glucosides, *digitalin* and *digitaleïn*. Of these, digitonin is useless as a remedy for heart disease, and, moreover, causes severe local inflammation, whilst digitoxin is unsuitable as a drug on account of its complete insolubility in water. The other two would be suitable if prepared pure. The digitaleïn of Schmiedeberg is a mixture; not so, however, his digitalin, which is a chemical compound, and is now prepared pure, according to the author's directions, by Boehringer, of Waldhof, and sold under the name of "*Digitalin verum*." This drug is perfectly uniform in its operation, gradually producing cessation of the heart's action, but no injurious secondary effects. Other preparations, such as "*Digitalinum crystallisatum*" and "*D. pur. pulv.*," are impure, and consequently irregular and often injurious in their action. The first of these, indeed, is nearly pure digitonin.

"*Digitalin verum*" is an amorphous, white powder, which is insoluble in chloroform and in ether, swells up in water, and dissolves in it to the extent of 1 part in 1000. 50 per cent. alcohol dissolves 1 part in 100, absolute alcohol still more. The pure substance has but a feebly bitter taste. As tests for its purity, the following may be used:—(1) a few particles placed in a test-tube with 2 c.c. of 10 per cent. aqueous potash should remain white for at least one minute; presence of the other amorphous glucosides causes an immediate yellow coloration. (2) It is stirred with water to a thin paste, 22 parts of amyl alcohol added, with shaking, for every 100 of water used, and the whole allowed to remain in a corked flask; if digitonin is present, it separates out within 24 hours in small, crystalline agglomerates. When heated with strong hydrochloric acid, best with the addition of 50 per cent. alcohol, digitalin is converted into *digitaligenin*, $C_{16}H_{22}O_2$, dextrose, and *digitalose*, $C_7H_{14}O_5$, a sugar which could not be obtained crystalline, but which, when oxidised with bromine, yields *digitalonic lactone*, $C_7H_{12}O_5$. This substance crystallises in fine, colourless prisms, easily soluble in water and alcohol, sparingly in ether. It begins to liquefy at 130°, and melts completely at 138—139°. If it is heated with aqueous soda, and the diluted solution treated with silver nitrate, silver digitalonate, $C_7H_{13}O_6Ag$, crystallises out in tiny needles. C. F. B.

Preparation of Digitogenin. By H. Kiliani (*Arch. Pharm.*, **230**, 261—262).—The method previously given should be modified by carrying out the hydrolysis in alcoholic solution. Digitonin, $C_{27}H_{46}O_{14} + 5H_2O$ (1 part), is heated with 93 per cent. alcohol (8 parts) and concentrated hydrochloric acid of sp. gr. 1·19 (2 parts) for $1\frac{1}{2}$ hours in a reflux apparatus on the water-bath, and the mixture allowed to cool slowly. The digitogenin which separates out, to the extent of about 25 per cent. of the digitonin employed, is removed, the filtrate saturated with chalk, the greater part of the alcohol distilled off, and the residue diluted with water and shaken out with chloroform. The chloroform extract is dried with sodium sulphate, the chloroform distilled off, and the residue crystallised from 93 per cent. alcohol; by this means a further yield of 5 per cent. of digitogenin is obtained. C. F. B.

Cascarin. By Leprince (*Compt rend.*, **115**, 286—288).—*Cascarin*, $C_{12}H_{10}O_5$, is an orange-yellow, crystalline substance obtained from the bark of *Rhamnus prushiana* (*Cascara sagrada*).

An infusion of the dry, powdered bark in boiling, dilute, aqueous sodium carbonate is treated with dilute sulphuric acid to precipitate impurities, and evaporated to dryness, preferably in a vacuum. The residue, after further drying at 60°, is extracted with acetone, the extract treated with sulphuric acid, and, after some time, the solution is poured into a large quantity of warm water. After 24 hours, a greenish-brown deposit settles, and this, on repetition of the treatment, yields cascarin.

Cascarin crystallises in prismatic needles, and is odourless and tasteless. It is insoluble in water, sparingly soluble in chloroform, and easily in alcohol, alcohol-ether, and alkalis, forming purple-red solutions with the last named. It chars at 200°, and melts with decomposition at 300°. When fused with potash, it yields phloroglucol. Jn. W.

Tetravinylpyridine. By G. Karau (*Ber.*, **25**, 2776—2777).—From the fraction 275—290° obtained in the preparation of γ-ethylpyridine, the author has isolated a *tetravinylpyridine*, $C_5NH(C_2H_3)_4$. It is a pale yellow oil boiling at 276—278°; its sp. gr. is 1·0515 at 0°. The *platinochloride* forms orange-yellow, silky needles, sparingly soluble in water, and melting at 175°; the *aurochloride*, pale yellow needles melting at 148°; the *mercurochloride*, long, white, glistening needles melting at 146°. L. T. T.

Piperidine Compounds. By R. Varet (*Compt. rend.*, **115**, 335—337; compare Abstr., 1891, 732 and 838).—*Piperidine argento-iodide*, C_5NH_{11},AgI, is made by heating piperidine with silver iodide in a reflux apparatus at 100° until the iodide has dissolved. The liquid is filtered, and, while still warm, deposits the argento-iodide in slender, transparent needles. Piperidine argento-iodide is blackened by air and light, and is decomposed into its proximate constituents by heat in the absence of light. It is also decomposed by water. *Piperidine argento-bromide*, $2C_5NH_{11},AgBr$, is prepared in the same way at 80°. It crystallises in needles, and is decomposed by water. It

is much more stable than the corresponding pyridine compound (*loc. cit.*). *Piperidine argento-chloride*, $2C_5NH_{11},AgCl$, obtained in the same way, crystallises in prismatic needles, is decomposed by water, and is blackened by light. It is unstable in the presence of air. *Piperidine argento-cyanide*, $2C_5NH_{11},AgCN$, is also made as above. It crystallises in transparent needles, is unstable in presence of air and light, and, when heated, gives off piperidine and cyanogen, the silver being left behind in mirror form. JN. W.

Oxidation of Piperidine by Hydrogen Peroxide. By R. WOLFFENSTEIN (*Ber.*, **25**, 2777—2785).—When pyridine is treated with double the quantity of hydrogen peroxide in 3 per cent. solution, it quickly becomes neutral and then acid, and leaves, on evaporation, a syrup smelling of fatty acids. If the residue is extracted with chloroform, and the extract evaporated and boiled with baryta-water, piperidine and ammonia are evolved, leaving a residue of barium glutarate. The formation of the latter by the oxidation of piperidine may be readily understood; the imido-group is eliminated, and the two methylene groups previously combined with it are oxidised to carboxyl. The portion insoluble in chloroform also consists chiefly of glutaric acid. If the chloroform extract is distilled, it undergoes decomposition, the chief portion passing over at 270°, and becoming solid on cooling; it crystallises from alcohol in lustrous tablets, and consists of *glutarimide*, $CH_2<\begin{matrix}CH_2\cdot CO\\CH_2\cdot CO\end{matrix}>NH$, the manner of formation of which is also manifest; it is a true derivative of piperidine, and has poisonous properties. There is also obtained in the distillation a small quantity of oil which shows the pyrroline reaction, and may be a methylpyrrolidine.

If piperidine is treated with a quantity of hydrogen peroxide sufficient only to add 1 atom of oxygen to the molecule, the product, after 24 hours, no longer smells of piperidine, but has a slightly basic reaction and strongly reducing properties. It is purified by distillation in a current of superheated steam, conversion into the platinochloride and then by the action of hydrogen sulphide into the hydrochloride, which has the composition $C_5H_{12}NOCl$, and gives all the characteristic reactions of an aldehyde. It must therefore be the hydrochloride of *δ-amidovaleraldehyde*, $NH_2\cdot CH_2\cdot CH_2\cdot CH_2\cdot CH_2\cdot CHO$, the piperidine ring having been split between the imido- and one of the methylene groups, and the latter oxidised to the aldehyde group. The free amidovaleraldehyde is obtained by the action of potassium carbonate on the salts, and on evaporating the ethereal solution crystallises in white plates; it melts at 39°, and is exceedingly soluble in water and light petroleum; the *hydrochloride* crystallises from acetone in monosymmetric crystals, the *hydrobromide* melts at 130°, and the *hydriodide* is a syrup. When the base is heated alone or with solid potash, it loses the elements of water, forming *tetrahydropyridine*. The latter is a strong base which absorbs carbonic anhydride from the air, has an odour intermediate between that of pyridine and piperidine, and, on distillation, undergoes gradual decomposition; its *aurochloride*, $C_5H_9N,HAuCl_4$, is microcrystalline, melts at 141°, and is fairly

soluble in water and alcohol; the *platinochloride* forms small, thick prisms, and the *hydrochloride* and *hydrobromide* melt at 230° and 178° respectively, both previously undergoing decomposition.

Nicotine, as already shown by Pinner and the author (this vol., p. 1010), when treated with hydrogen peroxide, also yields an acid containing an additional atom of oxygen; it has strongly reducing properties, and, on heating, loses water, forming dehydronicotine. The above reactions therefore form additional evidence in favour of the presence of the piperidine ring in nicotine.

If piperidine is mixed with an equal weight of hydrogen peroxide, and allowed to remain for some time, crystals separate, having the composition C_5H_9NO, and melting at 129°; the molecular weight agrees with the above formula, and the substance does not form a nitroso-derivative, but gives the violet phenol reaction with ferric chloride, and must therefore be an *α-hydroxypiperidine*, $CH_2<\begin{matrix}CH_2\cdot C(OH)\\CH_2-\!-CH_2\end{matrix}>N$. It is isomeric with Schotten's piperidone, $CH_2<\begin{matrix}CH_2\text{-}CO\\CH_2\cdot CH_2\end{matrix}>NH$, and may also be obtained by oxidising amidovaleraldehyde with cupric acetate.

Ozone acts on piperidine in the same manner as hydrogen peroxide, but is less active. Pyridine is only attacked with difficulty by hydrogen peroxide, and yields formic acid simply. H. G. C.

Nipecotinic Acid. By A. Ladenburg (*Ber.*, **25**, 2768—2772).—*Nipecotinic acid*, $COOH\cdot C_5NH_{10}$, obtained from the hydrochloride (Abstr., 1891, 735), yields hard, white, and highly refractive crystals. It is exceedingly soluble in water, sparingly so in methyl alcohol, and insoluble in alcohol or ether. It melts at 249—250°. It only shows decided acid characters when in concentrated solutions, and an amorphous deliquescent *sodium* salt was the only salt which could be obtained. On the other hand, as a base it forms a series of crystalline double salts. The *platinochloride* yields orange-red prisms melting at 212—213° (corr.); the *aurochloride* golden-yellow needles melting at 197° (corr.); the double salt with mercuric chloride,

$$C_6H_{11}NO_2,HCl,5HgCl_2,$$

is crystalline, and melts at 229—231°, but begins to decompose at 100°; the *bismuthoiodide* forms ruby-red crystals. That this acid is a secondary amine is shown by the formation of a *nitroso*-derivative, $COOH\cdot C_5NH_9\cdot NO$, which crystallises in prisms, and melts at 111—112°. When the sodium salt is heated with methyl iodide (1 mol.) at 100°, and the product obtained is treated with silver chloride, *methyl nipecotinate hydrochloride*, $COOMe\cdot C_5NH_{10},HCl$, is formed. It is soluble in alcohol and ether, crystallises in needles, and melts at 215—217°. The *platinochloride* crystallises in plates melting at 207—208°. If excess of methyl iodide is employed, a *dimethyl hydrochloride* (*methyl ν-methylnipecotinate hydrochloride*) is obtained as a syrupy mass, which yields a crystalline *platinochloride*, melting at 233—235°. This is probably identical with the platino-salt obtained by Jahn from dihydroarecoline (this vol., p. 739).

L. T. T.

Isonipecotinic Acid. By A. LADENBURG and G. KARAU (*Ber.*, **25**, 2772—2775).—Isonicotinic acid, obtained by the oxidation of γ-ethylpyridine, is reduced by means of sodium and amyl alcohol, and the acid formed is purified by conversion into the nitrosamine, which, after crystallisation, is reconverted into the acid. *Isonipecotinic acid*, $COOH{\cdot}C_5NH_{10}$, is easily soluble in water, insoluble in absolute alcohol, crystallises in needles, and remains solid at 320°, although it begins to blacken at 300°. Its concentrated aqueous solution has a slightly acid reaction. The *nitroso*-derivative crystallises in glistening, white needles, melts at 101°, and decomposes at 110°; it is easily soluble in water and alcohol, sparingly in ether. The *hydrochloride* crystallises in long, transparent prisms, soluble in water, sparingly so in absolute alcohol, and melts with decomposition at 228°. Its crystals belong to the rhombic system, giving the axial measurements $a : b : c = 0{\cdot}9217 : 1 : 0{\cdot}9787$. The *hydrobromide* and *hydriodide* form small, white needles, soluble in water and dilute alcohol. The *platinochloride* crystallises in small, yellow prisms, blackens at 230°, and melts at 239°. No well characterised metallic salts could be obtained, the alkaline salts being exceedingly deliquescent. L. T. T.

Piperidinecarboxylic Acids. By A. LADENBURG (*Ber.*, **25**, 2768—2775).—The three theoretically possible piperidinecarboxylic acids having now been prepared, namely, pipecolinic, nipecotinic, and isonipecotinic acids (see two preceding abstracts, and this vol., p. 735), it is found that none of them are identical with the two natural acids, hygric acid (Abstr., 1891, 586), and Zucco's acid from chrysanthemine. Whether these two natural acids are true piperidinecarboxylic acids, are true isomerides, and if so, what the character of their isomerism is, cannot yet be determined. L. T. T.

Phenyllutidinedicarboxylic Acid and Phenyllupetidinedicarboxylic Acid. By L. KIRCHNER (*Ber.*, **25**, 2786—2791).—*Phenyllutidinedicarboxylic acid*, $C_5NMe_2Ph(COOH)_2$, is obtained from Schiff and Puliti's ethyl hydrophenyllutidinedicarboxylate by oxidising it with nitrous acid, treating the product with sodium carbonate, and hydrolysing the ethyl salt thus obtained. The acid separates from the alkaline solution on the addition of an acid, as a pale-yellow sandy precipitate, which, when slowly crystallised from aqueous solution, forms fern-like aggregates of long, flat needles, and melts at 280° with decomposition. The *hydrochloride*, $C_5NMe_2Ph(COOH)_2,HCl$, forms slender, white needles, and is very unstable; the *mercurochloride* crystallises in small, transparent, pointed needles, blackens at 250°, and melts at 261°. The *copper* salt forms a bluish-green, amorphous precipitate, and the *silver* salt crystallises in small, transparent needles, which are very susceptible to the action of light, and blacken at 215°; the *barium* and *calcium* salts are much more stable, and both crystallise with 7 mols. H_2O. The *dimethyl* salt, $C_5NMe_2Ph(COOMe)_2$, crystallises in extremely slender needles or scales, is insoluble in water, and melts at 139—140°; its *aurochloride*, $C_5NMe_2Ph(COOMe)_2,HAuCl_4$, forms yellow, sparingly soluble needles, and melts with decomposition at 151°.

To convert the acid into the hexahydro-derivative, it is treated with sodium in amyl alcohol solution, and the reduced compound separated from unaltered acid by conversion into the *nitroso-compound*, which forms thick, white needles, melting with decomposition at 190°; it is reconverted into phenyllupetidinedicarboxylic acid by the action of hydrogen chloride, the excess of the latter causing the formation of the *hydrochloride*, $C_5NH_6Me_2Ph(COOH)_2,HCl + H_2O$, which crystallises from hydrochloric acid in small, lustrous needles, becomes brown at 275°, and decomposes completely at 280°. The free *phenyllupetidinedicarboxylic acid*, $C_5NH_6Me_2Ph(COOH)_2$, could not be isolated, as it so readily undergoes decomposition; its *aurochloride* and *mercurochloride* are oils; the *copper* and *silver* salts amorphous precipitates, and the *mercury* salt,

$$C_5NH_6Me_2Ph(COO)_2Hg,$$

a crystalline compound melting at 136°. The alkyl salts cannot be prepared by passing hydrogen chloride into an alcoholic solution of the hydrochloride, but the sodium salt, when heated with an excess of methyl iodide, yields the *methiodide* of the *dimethyl salt* as a thick, pale-yellow oil, which, on treatment with silver chloride, forms the corresponding *methochloride*, $C_5NH_6Me_2Ph(COOMe)_2,MeCl$, the *platinochloride* and *aurochloride* of which are amorphous, insoluble compounds, the latter having the melting point 68°. The *ethiodide* of the *diethyl salt* and the corresponding *ethochloride* are obtained in a similar manner; the latter forms an *aurochloride*, which crystallises in small hard cubes, sinters at 157°, and melts at 164°, and a *platinochloride* which forms crystalline nodules, melts at 165°, and decomposes at 180°. H. G. C.

Dimethyldipiperidyl. By A. Ladenburg (*Ber.*, **25**, 2792—2794). —When 1-methylpiperidine is treated with ethylene bromide, first at 0°, and finally at 250°, for two hours, it behaves in a similar manner to piperidine (*Ber.*, **4**, 738), and is converted into a derivative of dipiperidyl. After removing unaltered ethylene bromide, the product is made alkaline, and distilled in a current of steam, the unaltered methylpiperidine passing over first, and then the less volatile product of the reaction. After purification, the latter forms a liquid boiling at 265° (corr.), which from the analysis and vapour density has the formula $C_{12}H_{24}N_2$, and must therefore be a *dimethyldipiperidyl*. It unites with the moisture of the air, forming a hydrate crystallising in cube-like crystals, the water being again given off in dry air. The *hydrochloride*, $C_{12}H_{24}N_2,2HCl$, forms colourless crystals, stable in the air; the *platinochloride* separates in reddish-yellow plates, even from very dilute solutions, and melts at 236°, previously becoming dark; the *aurochloride*, *mercurochloride*, and *picrate* are also crystalline compounds.

An attempt was made to eliminate the methyl groups, and thus convert the compound into dipiperidyl; the elimination proceeds with considerable difficulty, the chief product of the reaction being piperidine. H. G. C.

Ketones of the Quinoline Series. By L. Berend and E. Thomas (*Ber.*, **25**, 2548—2549).—The authors endeavoured to obtain paracetylquinoline from paramidoacetophenone by Skraup's method, but without success, probably because at the temperature of the reaction the sulphuric acid acts both as a sulphonating and as an oxidising agent; by Doebner's method, however, a satisfactory yield of *paracetylquinaldine*, $C_{10}NH_8Ac$, may be obtained; it crystallises in delicate, silky needles, melts at 92°, and boils without decomposition at 312—320° (uncorr.). The *platinochloride*, $(C_{12}NH_{11}O)_2,H_2PtCl_6 + 3H_2O$, forms yellow, prismatic needles, readily soluble in hot water, and the *picrate*, $C_{12}NH_{11}O,C_6H_3N_3O_7$, forms similar crystals melting at 208—211°. Paracetylquinaldine also combines with phenylhydrazine to form the *hydrazone*, which crystallises from dilute alcohol in reddish-yellow, prismatic needles, and melts at 193°. H. G. C.

Amidoquinolines. By J. Ephraim (*Ber.*, **25**, 2706—2710; compare Abstr., 1891, 1509).—*2′-Phenylhydrazolepidine*,

$$C_9NH_5Me{\cdot}N_2H_2Ph,$$

obtained by heating 2′-chlorolepidine with phenylhydrazine (2 mols.), crystallises from alcohol in white needles, and melts at 197°; when dissolved in glacial acetic acid and oxidised with ferric chloride, it yields the *azo*-derivative, $C_9NH_5Me{\cdot}N_2Ph$, which forms orange-red needles, and melts at 98°. When the hydrazo-compound is boiled with hydriodic acid and amorphous phosphorus for an hour, it decomposes into aniline and Klotz's α-amidolepidine (Abstr., 1888, 1113). 2′-Chlorolepidine does not react with carbamide, but when heated with anthranilic acid, a basic compound, $C_{17}H_{12}N_2O$, is obtained, forming a picrate melting at 217°.

β-Naphthachloroquinaldine, $C_{10}H_6<\begin{matrix}N\text{—}CMe\\ |\\ CCl{:}CH\end{matrix}$, prepared by heating Knorr's β-naphthahydroxyquinaldine with phosphorus oxychloride (2 parts), melts at 159°. When the chloro-compound is heated with aniline (2 mols.), it yields the *anilide*, $C_{13}NH_7Me{\cdot}NHPh$, which crystallises from alcohol in white needles, and melts at 168°; if heated with an equal weight of phenylhydrazine, the *hydrazo*-derivative, $C_{13}NH_7Me{\cdot}N_2H_2Ph$, which forms yellowish-white crystals, and melts at 189°, is obtained. 1′-Chloro-3′-phenylisoquinoline, when heated with aniline, yields the *anilido*-compound, $C_9NH_5Ph{\cdot}NHPh$, melting at 126°, and the *phenylhydrazo*-derivative, $C_9NH_5Ph{\cdot}N_2H_2Ph$, melting at 185°, when heated at 140° with phenylhydrazine. A. R. L.

Alkyl and Alkylene Derivatives of Cinchonic Acid and Alkylene Derivatives of Cinchoxinic Acid. By A. Claus (*Annalen*, **270**, 335—359; compare this vol., p. 1249).—The betaïne of benzylquinoline-γ-carboxylic acid (not β-carboxylic acid, as given by Claus and Muchall, Abstr., 1885, 560) forms monosymmetric crystals, $a : b : c = 0{\cdot}9185 : 1 : 1{\cdot}3413$, $\beta = 95° 41′$, and has the composition $C_{10}H_6NO_2{\cdot}C_7H_7 + 3H_2O$; it separates from glacial acetic acid in yellow, seemingly asymmetric crystals, which retain some of the solvent, and melt at 71°; on oxidation with potassium permanganate,

it yields benzoic acid, benzoylorthamidobenzoic acid and other products.

Benzylidenecinchonic acid, $COOH{\cdot}C_9H_6N{:}CHPh$, is formed when the betaïne is treated with dilute potash and the solution acidified with dilute hydrochloric acid; it crystallises from ether in dark yellow needles, and melts at 218°. It undergoes oxidation so very readily on exposure to the air, that even on recrystallisation from ether it is partially converted into a red, resinous substance; when the residue obtained by evaporating its ethereal solution is treated with soda, the coloured, resinous products readily pass into solution, and benzylidenecinchoxinic acid remains undissolved.

Benzylidenecinchoxinic acid, $O<\begin{matrix}CHPh{\cdot}N{:}C_9H_6{\cdot}COOH\\ |\\ CHPh{\cdot}N{:}C_9H_6{\cdot}COOH\end{matrix}$, purified by means of its barium salt, separates from glacial acetic acid in colourless, lustrous needles, and from chloroform in yellow, well-defined, monosymmetric efflorescent crystals, $a : b : c = 1{\cdot}5993 : 1 : ?$, $\beta = 111° 7'$. It melts at 220°, and dissolves freely in alcohol, ether, chloroform, acetone, and glacial acetic acid, but is insoluble in boiling water; on oxidation with nitric acid of sp. gr. 1·1, it yields terephthalic acid. Its alkali salts are very readily soluble in water, and separate from alcoholic ether in colourless needles. The *barium* salt, $C_{34}H_{24}N_2O_5Ba + 3H_2O$, crystallises in colourless needles, and is only moderately easily soluble in cold water, insoluble in alcohol. The *calcium* salt, $C_{34}H_{24}N_2O_5 + 4H_2O$, crystallises from hot water in flat, nacreous needles. The *silver* salt, $C_{34}H_{24}N_2O_5Ag_2$, crystallises in flat needles, and is stable in the light. The *ethyl* salt, $C_{34}H_{24}N_2O_5Et_2$, prepared by passing hydrogen chloride into an alcoholic solution of the acid, crystallises from ether in lustrous needles, and melts at 120°.

Cinchonic acid ethobromide, $C_{10}H_7NO_2,EtBr$, prepared by heating cinchonic acid with ethyl bromide at 140°, crystallises from alcoholic ether in colourless needles, melts at 237°, and is very readily soluble in water, from which it separates in large, prismatic, efflorescent crystals. The *methiodide*, $C_{10}H_7NO_2,MeI$, crystallises from water in large, red needles, melts at 224°, and is only very sparingly soluble in chloroform, and almost insoluble in ether. The *methochloride*, $C_{10}H_7NO_2,MeCl$, is readily soluble in alcohol, and moderately easily in water, from which it separates in large, yellow, prismatic crystals melting at 243°. The *methobromide* is more sparingly soluble in cold water, crystallises in lustrous, colourless needles, and melts at 262°.

Cinchonic acid methylbetaïne, $C_{11}H_9NO_2$, is easily obtained by treating the methyl halogen compound, with silver oxide, in cold aqueous solution. It crystallises from hot alcohol in slender, lustrous needles, begins to sinter at 180°, melts at 236° with decomposition, and is insoluble in ether and chloroform, but very readily soluble in water; it has an intensely bitter taste, and, with ferric chloride, its aqueous solution gives a red coloration on warming.

Methylenecinchonic acid, $CH_2{:}C_9NH_6{\cdot}COOH$, is best obtained by treating a concentrated solution of the preceding compound with concentrated potash in the cold, covering the mixture with ether, and then acidifying with hydrochloric acid; the solution should be kept cold,

and agitated as little as possible to prevent the oxidation of the acid; on evaporating the dried ethereal solution under reduced pressure, the acid is deposited in brownish-yellow needles, mixed, however, with colourless crystals of methylenecinchoxinic acid. It crystallises in yellow needles, melts at 210°, dissolves freely in alcohol and ether, and very readily undergoes oxidation; on exposure to the air, the crystals turn dark brown or blue, and if, after some time, they are treated with ether, the coloured portions dissolve, leaving colourless crystals of methylenecinchoxinic acid; by evaporating the brown ethereal solution of the intermediate oxidation products, and submitting the residue to the same series of operations, the whole of the methylenecinchonic acid can be transformed into methylenecinchoxinic acid.

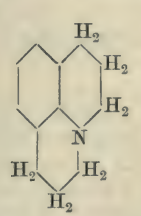
Methylenecinchoxinic acid, $O<\begin{matrix}CH_2\cdot N{:}C_9H_6\cdot COOH\\ CH_2\cdot N{:}C_9N_6\cdot COOH'\end{matrix}$ can also be obtained by boiling the preceding compound with water in presence of air; it crystallises from hot alcohol and glacial acetic acid in lustrous needles, melts at 249°, and is insoluble in ether and chloroform, and only very sparingly soluble in cold water, but readily in boiling water; it sublimes without decomposition. The *sodium* salt, $C_{22}H_{16}N_2O_5Na_2 + 10H_2O$, is readily soluble in water and alcohol, and separates from water in long, yellow, transparent, efflorescent prisms. The *potassium* salt, $C_{22}H_{16}N_2O_5K_2 + 3H_2O$, crystallises in small needles, and is readily soluble in water and alcohol. The *silver* salt, $C_{22}H_{16}N_2O_5Ag_2$, is a colourless, crystalline compound, insoluble in water.

Cinchonic acid ethiodide, $C_{10}H_7NO_2,EtI$, crystallises from alcohol in orange-yellow needles, melts at about 200° with decomposition, and is soluble in water.

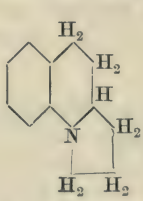
Cinchonic acid ethylbetaïne, $C_{12}H_{11}NO_2 + 2H_2O$, prepared by treating the ethiodide with silver oxide in cold aqueous solution, separates from water in lustrous, colourless crystals which melt at 90—92°, and lose their water at 110°, the anhydrous substance melting at 199° with decomposition; it is readily soluble in water and alcohol, its aqueous solution having a bitter taste, and giving, with ferric chloride, an intense red coloration on warming.

Ethylidenecinchonic acid, $CHMe{:}C_9NH_6\cdot COOH$, is formed when the preceding compound is treated with potash, and is isolated as described in the case of the homologue. It crystallises from ether in brownish-yellow, transparent prisms, and readily undergoes oxidation on exposure to the air in a moist condition. The *silver* salt has the composition $C_{12}H_{10}NO_2Ag$.

Ethylidenecinchoxinic acid, $O<\begin{matrix}CHMe\cdot N{:}C_9H_6\cdot COOH\\ CHMe\cdot N{:}C_9H_6\cdot COOH'\end{matrix}$, obtained by boiling a solution of ethylidenecinchonic acid in dilute alcohol for a long time in presence of air, crystallises from hot alcohol in colourless needles, melts at 206°, and is readily soluble in warm alcohol, but only very sparingly in chloroform, and almost insoluble in water and ether; it sublimes unchanged in long, colourless needles. The *sodium* salt, $C_{24}H_{20}N_2O_5Na_2 + Aq$, is readily soluble in alcohol and water, from which it separates in well-defined, efflorescent crystals. The *potassium* salt forms short, transparent prisms, and dissolves freely in



alcohol and water. The *silver* salt, $C_{24}H_{20}N_2O_5Ag_2$, is a moderately stable, crystalline powder.



Cinchonic acid propobromide, $C_{10}H_7NO_2,PrBr$, crystallises from alcoholic ether in lustrous, colourless needles, melts at 218° with decomposition, and is readily soluble in alcohol and water. The corresponding additive products with isobutyl bromide and amyl iodide could not be obtained. F. S. K.

Action of Trimethylene Chlorobromide on Aromatic Amines and Amides. By G. Pinkus (*Ber.*, **25**, 2798—2806).—Gabriel and his pupils have shown that trimethylene chlorobromide acts on thioamides with formation of penthiazolines having the general formula $RC\leqslant^{S\cdot CH_2}_{N\cdot CH_2}>CH_2$. In the present paper, the author describes the results obtained by substituting amides for the thio-derivatives.

Formanilide and trimethylene chlorobromide react with one another at the boiling point of the latter, forming a mixture of two bases having the formulæ $C_{13}H_{12}N_2$ and $C_{12}H_{15}N$ respectively, carbonic oxide being also evolved. The former base is identical with the methenyldiphenylamidine described by Wallach, its formation being brought about by the action on the excess of formanilide of the hydrogen chloride set free during the process. The second base may be obtained much more readily and unmixed with the amidine by substituting aniline for formanilide.

The base contains a tertiary nitrogen atom, and hence both hydrogen atoms of the amido-group have been replaced, one halogen atom of each molecule of the chlorobromide having been eliminated with each of these hydrogen atoms; the remaining halogen atoms would most probably combine with hydrogen atoms in the benzene nucleus forming a compound having one of the following constitutional formulæ:—

That the base is in reality a derivative of tetrahydroquinoline is proved by the fact that it may also be obtained by the action of trimethylene chlorobromide on that compound; in order to ascertain which of the above formulæ is correct, the action of the chlorobromide on formorthotoluidide and formoparatoluidide was examined, the result showing that whilst the para-derivative readily yields an analogous base, the ortho-derivative behaves in a different manner. Hence the first of the above formulæ must be correct, for, as will be seen, no such compound can be formed if the ortho-position is already occupied, as it is in formorthotoluidide.

The base $C_{12}H_{15}N$ is also formed in small quantity by the re-

duction of Reissert's α-keto-γ-juloline (this vol., p. 883); this fully agrees with the above constitution, and the name of the substance, therefore, becomes, in accordance with Reissert's system, *julolidine*.

Julolidine is a colourless, crystalline mass which melts at 40°, boils with considerable decomposition at 280°, and becomes brownish-red after a time; the *hydrochloride*, $C_{12}H_{15}N,HCl$, crystallises in white prisms, is partially dissociated by water, and melts at 218°; the *hydriodide* melts at 219—222°, the *picrate* at 165°, and the *platinochloride* at 220°. The base gives a deep blood-red coloration with all oxidising agents; purple-red needles having a metallic lustre, sometimes separate out, but gradually become colourless. Towards methyl iodide, julolidine behaves as a tertiary base yielding a *methiodide* which forms colourless crystals, melts at 186°, and is not attacked by potash.

The base obtained from formoparatoluidide is an oil, but yields a crystalline *hydriodide*, $C_{12}NH_{14}Me,HI$, and shows reactions similar to those of julolidine. Formorthotoluidide, on the other hand, yields, with trimethylene chlorobromide, a salt having the formula $C_6H_4Me\cdot N(C_3H_6X)_2,HX$, X being partly chlorine and partly bromine. This substance only loses the remainder of the halogens with great difficulty, and then forms tetrahydrorthotoluquinoline, $C_{10}H_{13}N$ (compare Ziegler, Abstr., 1888, 609). The free base melts at 252°, the *hydrochloride* at 210°, the *picrate* at 168°, the *platinochloride* at 212°, and the *nitroso*-derivative at 136°.

Paramethoxyquinoline is also attacked by trimethylene chlorobromide with formation of *paramethoxyjulolidine*, $C_{12}NH_{14}\cdot OMe$, which is a pungent-smelling liquid; its *hydrochloride* separates from water in long needles, and from alcohol in compact crystals, melts at 188° with decomposition, and gives no coloration with ferric chloride; the *platinochloride* melts at 209—210°.

The action of trimethylene chlorobromide on benzenesulphanilide and of ethylene bromide on benzylamine was also examined, but in the first case no reaction takes place, and very little in the second.

H. G. C.

Cincholine and Fluoroline. By O. Hesse (*Annalen*, **271**, 95—100; compare Abstr., 1882, 1114; and Weller, Abstr., 1887, 979).—Cincholine, $C_{10}H_{21}N$, obtained from paraffin oil, and purified by means of its oxalate, is a highly refractive oil, with an odour recalling that of pyridine, and specifically lighter than water; it boils at 236—238°, and dissolves freely in ether, chloroform, and alcohol, but is almost insoluble in water. The oxalate, $(C_{10}H_{21}N)_2,C_2H_2O_4$, crystallises in colourless plates, and is only sparingly soluble in cold alcohol, and almost insoluble in cold water; the other salts do not crystallise.

Fluoroline, $C_{12}H_{13}N$, the volatile base previously described as hygrine, and supposed to have been obtained from (?) Trujillo coca (*Pharm. Zeit.*, 1887, 668) is probably derived from the coal-tar oil employed in extracting the alkaloïds, in spite of the fact that Giesel has also stated that the base can be obtained from Trujillo coca and from Java coca (*Pharm. Zeit.*, **36**, 420). It is a yellow oil, with a peculiar odour, like that of quinoline, and dissolves freely in ether,

alcohol, and chloroform, but only sparingly in cold water; it has a strongly alkaline reaction, and is readily soluble in dilute acids, the solutions showing a blue fluorescence. The *oxalate* crystallises in colourless needles, and is readily soluble in water and alcohol. The *hydrochloride* is crystalline and readily soluble in water. The *platinochloride*, $(C_{12}H_{13}N)_2,H_2PtCl_6 + 2H_2O$, crystallises in small, pale yellow needles, loses its water at 100°, and is only sparingly soluble in cold water. F. S. K.

Glyoxaline. By F. Rung and M. Behrend (*Annalen*, **271**, 28—40). —The following experiments were undertaken with the object of throwing some light on the constitution of glyoxaline, but they were brought to a conclusion by the publication of Bamberger's papers (this vol., p. 632) on benzimidazoles.

Diazobenzeneglyoxaline, $C_3H_3N_2{\cdot}N_2Ph$, prepared by treating glyoxaline with diazobenzene chloride in ice-cold, aqueous solution, crystallises from dilute alcohol in red needles, melts at 177—178°, and is readily soluble in alcohol, ether, and chloroform, but only sparingly in water, and almost insoluble in light petroleum; it resinifies on exposure to the air, and is decomposed by boiling acids.

A compound of the composition $C_3H_3N_3O_2$, probably a *nitroglyoxaline*, is produced when glyoxaline is heated with a mixture of nitric acid and concentrated sulphuric acid; it separates from boiling alcohol in colourless needles, and is sparingly soluble in hot water and alcohol, insoluble in ether and chloroform, but soluble in glacial acetic acid and hydrochloric acid; it dissolves in alkalis yielding yellow solutions, from which it is precipitated unchanged on the addition of an acid; it forms a sparingly soluble silver derivative.

A crystalline additive product is formed when methylglyoxaline is warmed with ethyl chloracetate; it melts at 196—197°, and is very readily soluble in water; on adding platinic chloride to an aqueous solution of this substance, a crystalline salt of the composition $(C_8H_{13}N_2O_2Cl)_2,PtCl_4$ is obtained.

Glyoxaline also combines with ethyl chloracetate, yielding a syrupy product which is very readily soluble in water; in its aqueous solution platinic chloride produces a crystalline precipitate of the composition $C_{22}H_{34}N_4O_8,PtCl_6$. When the original syrupy product is digested with silver oxide in aqueous solution, it is converted into a crystalline substance of the composition $C_7H_8N_2O_4$, which decomposes when heated above 230—235°, but without melting; as the same compound can be obtained by heating glyoxaline with chloracetic acid at 100°, and then treating the product with silver oxide in aqueous solution, its constitution is probably expressed by the formula

$$COOH{\cdot}CH_2{\cdot}C_3H_3N_2{<}\begin{matrix}CH_2-\\O{\cdot}CO\end{matrix}{>}.$$

When the methiodide or ethiodide of methylglyoxaline is boiled with concentrated potash, it is decomposed with liberation of methylamine, no ammonia being formed. Methylglyoxaline propochloride is decomposed by boiling potash, yielding methylamine and formic acid in molecular proportion; methylglyoxaline amylochloride also

gives methylamine, whilst benzylglyoxaline methiodide yields benzylamine. F. S. K.

Cinnoline Derivatives. By M. Busch and M. Klett (*Ber.*, **25**, 2847—2853; compare v. Richter, Abstr., 1883, 1105).—Hydroxycinnoline (*loc. cit.*) is thus prepared:—The calculated quantity of sodium nitrite solution is added to orthamidophenylpropiolic acid, suspended in a mixture of equal volumes of concentrated hydrochloric acid and water (10 parts), and the hydroxycinnolinecarboxylic acid thus obtained is converted into hydroxycinnoline. O. Fischer's harmine (Abstr., 1889, 730) is, perhaps, dihydrocinnoline, but cinnoline itself is unknown, and the authors' attempts to prepare it by the action of numerous reducing agents on both hydroxycinnoline and on the chloro-derivative have proved unsuccessful.

Chlorocinnoline, $C_6H_4<\begin{matrix}CCl:CH\\ |\\ N=N\end{matrix}$, is obtained by slowly adding hydroxycinnoline to phosphoric chloride (4 parts) mixed with some phosphorus oxychloride, subsequently heating the mixture on the water-bath for an hour, and pouring it on to ice, whereby an aqueous solution is obtained. After adding alkali to the latter, it is extracted with ether, the colouring matters being removed from the ethereal solution by treating it with animal charcoal. The compound crystallises from light petroleum in long, white needles, melts at 79°, and is very readily soluble in alcohol. The chlorine is displaced by hydroxyl even on boiling the compound with water, and when silver nitrate is added to its aqueous solution the theoretical amount of silver chloride is precipitated. The hydrochloride forms white needles, and melts at 151°. *Anilidocinnoline*, $C_6H_4<\begin{matrix}C\cdot NHPh\\ |\\ N=N\end{matrix}>CH$, formed by gently warming the chloro-derivative with aniline, crystallises in brownish, lustrous needles, melts at 232°, and is sparingly soluble in ether. *Paratoluidocinnoline* melts at 215°.

Ethoxycinnoline, $C_6H_4<\begin{matrix}C(OEt):CH\\ |\\ N=N\end{matrix}$, is obtained by gently warming hydroxycinnoline with sodium ethoxide in alcoholic solution; protracted heating causes decomposition. The compound crystallises from light petroleum in small, colourless, felted needles, melts at 106°, and is very readily soluble in water. A. R. L.

β-Succinylphenylhydrazide or 1-Phenyl-3 : 6-orthopiperazone. By A. Michaelis and R. Hermens (*Ber.*, **25**, 2747—2752).—*β-Succinylphenylhydrazide* or 1-*phenyl*-3 : 6-*orthopiperazone*,

$$\begin{matrix}CH_2\cdot CO\cdot NPh\\ |\\ CH_2\cdot CO\cdot NH\end{matrix},$$

is obtained by the action of succinic chloride on sodium phenylhydrazide. This substance (isomeric with Hotte's α-succinylphenylhydrazide) crystallises from hot water in transparent crystals melting at 199°. It reduces Fehling's solution when heated, and does not give the Bülow colour reaction with sulphuric acid and potassium chromate. It is sparingly soluble in cold water or boiling alcohol, readily

in boiling water or glacial acetic acid. It is soluble in aqueous alkalis and in ammonia, and does not form a nitroso-derivative, thus resembling Hotte's corresponding β-phthalylphenylhydrazide. When heated with excess of acetic anhydride, it yields the *monacetyl* derivative; this crystallises in colourless scales, which darken at 172°, and melt at 179°. It is very sparingly soluble in boiling water, more soluble in boiling alcohol. Cold dilute alkali does not dissolve it, but when hot causes its decomposition.

Attempts to produce the above piperazone by the hydrolysis of ethyl succinate phenylhydrazide proved unavailing, the α-hydrazide, $\begin{matrix}CH\cdot CO\\ |\\ CH\cdot CO\end{matrix}>N\cdot NHPh$, being formed.

Ethyl succinic chloride, $COOEt\cdot CH_2\cdot CH_2\cdot COCl$, was obtained by the action of phosphoric oxychloride on sodium ethyl succinate,

$$COOEt\cdot C_2H_4\cdot COONa.$$

It is a colourless, mobile, highly refractive liquid, boiling at 144° under 90 mm. pressure. It has a pungent smell, fumes in the air, and is only slowly decomposed by cold water. When distilled under atmospheric pressure, it is decomposed into ethyl chloride and succinic anhydride. When this chloride (1 mol.) is treated with phenylhydrazide (2 mols.), *ethyl succinate phenylhydrazide*,

$$COOEt\cdot C_2H_4\cdot CO\cdot NH\cdot NHPh,$$

is formed. This substance crystallises from hot water in white needles, soluble in alcohol, but only sparingly so in ether. It melts at 107°, reduces Fehling's solution, and shows the Bülow reaction. When it is dissolved in hot dilute potash and the solution, on cooling, acidified with hydrochloric acid, a substance of the formula $C_{20}H_{22}N_4O_3$ is formed, which crystallises in colourless needles melting at 137°, and reduces Fehling's solution. When heated to 170°, this compound yields Hotte's α-succinyl phenylhydrazide; and is, therefore, probably the anhydride, $O(CO\cdot C_2H_4\cdot CO\cdot NH\cdot NHPh)_2$. The authors find that when pure, Hotte's α-hydrazide crystallises at 158° (Hotte 155°).

L. T. T.

New Synthesis of Ketoquinazolines and Thioquinazolines. By M. Busch (*Ber.*, **25**, 2853—2860).—*Phenyltetrahydroketoquinazoline*, $C_6H_4<\begin{matrix}NH\cdot CO\\ |\\ CH_2\cdot NPh\end{matrix}$, separates, together with orthamidobenzylaniline hydrochloride, when a 20 per cent. solution of carbonyl chloride (0·5 mol.) in toluene is added to an ethereal solution of orthamidobenzylaniline; the mixture is then shaken with water, the solvent distilled off, and the compound crystallised from dilute alcohol. It crystallises from ethyl acetate in colourless, translucent, four-sided tables, melts at 189°, and is indifferent both towards acids and towards alkalis.

Phenyltetrahydrothioquinazoline, $C_6H_4<\begin{matrix}NH\cdot CS\\ |\\ CH_2\cdot NPh\end{matrix}$, is prepared by boiling orthamidobenzylaniline with carbon bisulphide (3 parts) and an equal volume of alcoholic potash, in a reflux apparatus, for an hour. After distilling off the liquid and crystallising the residue

from alcohol, the compound is obtained in colourless needles or large, translucent plates almost insoluble in ether; its melting point (about 245°) is not sharp. If heated with alcohol and mercuric oxide in a sealed tube at 150° for five hours, it gives the above-described keto-compound; whilst, on reduction with sodium ethoxide, phenyltetrahydroquinazoline (Abstr., 1890, 73), which is now found to melt at 119°, is produced.

Paratolyltetrahydroketoquinazoline, $C_6H_4<\begin{matrix}NH\cdot CO\\ |\\ CH_2\cdot N\cdot C_6H_4Me\end{matrix}$, melts at 218—220°, and *paratolyltetrahydrothioquinazoline*,

$$C_6H_4<\begin{matrix}NH\cdot CS\\ |\\ CH_2\cdot N\cdot C_6H_4Me\end{matrix},$$

at 235°. The latter yields the keto-compound on oxidation with mercuric oxide, whilst reduction with sodium ethoxide converts it into paratolyltetrahydroquinazoline (*loc. cit.*).

Tetrahydrothioquinazoline, $C_6H_4<\begin{matrix}NH\cdot CS\\ |\\ CH_2\cdot NH\end{matrix}$, is obtained from orth-amidobenzylamine and carbon bisulphide; it crystallises from alcohol in nodular aggregates of leaflets, and melts at 210—212°.

A. R. L.

Action of Formaldehyde on Orthodiamines. By O. Fischer and H. Wreszinski (*Ber.*, **25**, 2711—2715).—The tertiary anhydrobases (imidazoles), of which methylmethenylphenyleneamidine, melting at 33° (Abstr., 1889, 731), is the simplest member, are formed when an excess of formaldehyde is added to a faintly acid solution of an orthodiamine hydrochloride, the mixture being, after a while, rendered alkaline, and the base extracted with ether. If, however, the formaldehyde is added to a neutral solution of the orthodiamine, bases polymeric with the last-mentioned are obtained.

The *base*, $C_{16}H_{16}N_4$, is prepared by adding 50 per cent. formaldehyde (3 grams) to a hot solution of orthophenylenediamine (2 grams) in alcohol (15 grams), and boiling the mixture for a minute; it separates on adding water, and when crystallised from ether forms colourless, thick tables, melts at 144°, and is almost insoluble in water; it probably has the constitution $\begin{matrix}C_6H_4\cdot N\text{—}CH\cdot NMe\\ |\quad\quad\quad\quad\quad\quad|\\ NMe\cdot CH\cdot N\text{—}C_6H_4\end{matrix}$. The *platinochloride* forms yellow, lustrous needles, and melts at 240°. In a similar manner there are obtained from diamidotoluene [Me : $(NH_2)_2 = 1 : 3 : 4$], a base, $C_{18}H_{20}N_4$, melting at 222°, and from $\alpha\beta$-diamidonaphthalene a base, $C_{24}H_{20}N_4$, melting at 165°.

Methenylnaphthaleneamidine, $C_{10}H_6<\begin{matrix}NH\\ |\\ N\end{matrix}>CH$, is produced by boiling $\alpha\beta$-diamidonaphthalene with formic acid; it crystallises from ether in large plates, melts at 174°, and is sparingly soluble in water. A *methyl* derivative is obtained when the last-described base is heated under pressure with methyl iodide (1 mol.) and wood spirit (10 parts) for 5—6 hours; it is a bright, yellow oil, which boils at 286°, and its solution in alcohol exhibits a beautiful blue fluorescence.

A. R. L.

Nicotine. By A. Pinner (*Ber.*, **25**, 2807—2821).—By the action of bromine on free nicotine, large quantities of resinous products are formed; whilst the action of bromine on a solution of nicotine in acetic acid or hydrobromic acid gives rise in the first place to an oily additive product from which the bromine is eliminated by treatment with sulphurous acid. In acetic acid solution the reaction quickly goes further; hydrogen bromide is formed, and the product contains the two compounds $C_{10}H_8N_2Br_2$ and $C_{10}H_8N_2Br_2O_2$, of which the former yields the well crystallised perbromide, $C_{10}H_8N_2Br_2,HBr_3$, described by Huber (*Annalen*, **131**, 257), and Cahours and Etard (*Compt. rend.*, **90**, 1315; *Bull. Soc. Chim.*, **34**, 457); the latter yields a colourless hydrobromide, $C_{10}H_8N_2Br_2O_3,HBr$, formerly obtained in an impure condition by Laiblin.

The perbromide, $C_{10}H_8N_2Br_2,HBr_3$, is obtained by adding bromine ($3\frac{1}{2}$—4 parts), dissolved in acetic acid (4—5 parts), to a solution of nicotine in acetic acid (5—6 parts). The oily product first formed dissolves on allowing the mixture to remain, or on gently warming it at 50—60°. The perbromide crystallises from the clear solution after two days in monosymmetric, chrome-red scales or flat, yellowish-red needles, is easily soluble in warm acetic acid, sparingly so in water, melts at 163° with decomposition, smells of bromine, which it loses on drying, and is decomposed by boiling with water with evolution of bromine and production of a colourless solution, which probably contains the base as hydrobromide. The complete combustion of the substance is extremely difficult, and as the numbers obtained on analysis do not agree very well with those demanded by theory, the above composition was also proved by titrating the product with sulphurous acid, by estimating the amount of hydrogen bromide formed in the reaction with soda solution, and also by precipitation with silver nitrate. The results obtained in this way agree with those required by the formula given.

The free base, dibromodehydronicotine, $C_{10}H_8N_2Br_2$, is obtained by treating the perbromide with ammonia. The *hydrobromide* is very easily soluble in water. The *picrate*, $C_{10}H_8N_2Br_2,C_6H_2(NO_2)_3{\cdot}OH$, is obtained by heating the perbromide with water, and adding picric acid to the aqueous solution; also by adding bromine (6—8 atoms) to a solution of nicotine in hydrobromic acid, boiling until the mixture is free from bromine, and then adding picric acid, or by reducing the perbromide with sulphurous acid and adding picric acid. It crystallises from water in large, lustrous, highly refractive, yellow prisms, darkens at 177°, melts at 180°, and then decomposes with much frothing. The *platinochloride* crystallises in long, yellow needles, darkens at 200°, does not melt at 250°, and is very sparingly soluble in water.

Dibromodioxydehydronicotine hydrobromide, $C_{10}H_8N_2O_2Br_2,HBr$, is obtained by heating nicotine (10 grams) with aqueous hydrobromic acid (20 per cent., 25 grams) and bromine (25 grams) in a sealed tube for 10—12 hours on the water-bath. It crystallises from water in slender, white needles, or colourless, lustrous, flat prisms, begins to darken at 200°, decomposes on further heating, and is easily soluble in hot water, sparingly so in the cold. The *free base* is obtained by adding alkali to a solution of the salt. It is obtained in small, nodular

crystals, melts at 196° with decomposition, and is soluble in acids, alkalis, and the alkaline earths. When the free base is oxidised with alkaline permanganate, it yields nicotinic acid.

Dibromodehydronicotine, when treated with strong bases, yields methylamine, oxalic acid, and a compound containing nitrogen; the latter has not yet been isolated. The crystallised perbromide is treated with a slight excess of sulphurous acid, and to the colourless liquid thus obtained an excess of barium hydroxide is added, the mixture filtered, and then heated to boiling, and distilled with steam as long as the distillate is alkaline. Methylamine hydrochloride is easily obtained from the filtrate in the theoretical quantity, supposing that one nitrogen atom is eliminated in the form of methylamine, and barium oxalate is found in the residue.

The author is engaged in attempting to isolate the third decomposition product of dibromodehydronicotine. E. C. R.

Alkaloïds of Belladonna. By O. Hesse (*Annalen*, **271**, 100—126).—The greater part of this paper consists of a description of well-known salts of hyoscyamine, atropine, and hyoscine, and of a discussion of the results of other chemists' work on the alkaloïds of belladonna.

Hyoscine has the composition $C_{17}H_{21}NO_4$, and not $C_{17}H_{23}NO_3$, as supposed by Ladenburg and Merck; it melts at about 55°, and dissolves freely in ether, chloroform, and alcohol, but is only moderately easily soluble in water; its specific rotatory power in alcoholic solution at 15° is $[\alpha]_D = -13{\cdot}7°$.

The author proposes that Ladenburg's pseudotropine or hydroxytropine should be called *oscine;* the composition of oscine is $C_8H_{13}NO_2$, not $C_8H_{15}NO$. *Benzoyloscine*, $C_{15}H_{17}NO_4$, prepared by heating oscine at 80—100° with an equal weight of water and a large excess of benzoic anhydride, crystallises from chloroform in needles, melts at 59°, and is readily soluble in ether, alcohol, chloroform, and acids, and moderately easily in water. The *aurochloride*, $C_{15}H_{17}NO_4,HAuCl_4$, crystallises in small, yellow needles, and melts at 184°.

Atropamine platinochloride (compare Abstr., 1891, 228) crystallises in yellow scales, and melts at 203—204° with decomposition.

F. S. K.

Hyoscine (Scopolamine). By E. Schmidt (*Ber.*, **25**, 2601—2607).—A reply to Ladenburg (this vol., p. 1366).

Berberis Alkaloïds. Berberine and Hydroberberine. By E. Schmidt (*Arch. Pharm.*, **230**, 287—291).—The author has caused fresh experiments to be made which confirm and amplify those previously carried out by H. Schreiber (*Inaug. Diss.*, Marburg, 1888), and R. Gage (Abstr., 1890, 1012; and 1891, 332). These experiments were carried out by C. Link, and are described in the following abstract.

C. F. B.

Berberine and Hydroberberine. By C. Link (*Arch. Pharm.*, **230**, 291—320).—When an aqueous solution of berberine sulphate is treated with excess of bromine in the cold, berberine tetrabromide hydrobromide, $C_{20}H_{17}NO_4,Br_4,HBr$, is formed; but this, when heated at 100° or treated with cold alcohol, loses 2 atoms of bromine and

forms the dibromide hydrobromide, which, when boiled with alcohol, loses 2 atoms more, yielding berberine hydrobromide, $C_{20}H_{17}NO_4,HBr + 2H_2O$.

Hydroberberine tetrabromide hydrobromide, $C_{20}H_{21}NO_4,Br_4,HBr$, is formed when hydroberberine, either in sulphuric acid or in chloroform solution, is treated with bromine. When heated at 100°, or when boiled with alcohol, it is converted into the dibromide, $C_{26}H_{21}NO_4Br_2$, which in the latter case crystallises with $3H_2O$. The dibromide, when heated with alcoholic potash, loses CH_3Br, one of the two methoxyl groups being destroyed, and yields a compound $C_{19}H_{18}NO_4Br$, which is not a hydrobromide, for it does not give silver bromide with silver nitrate, but a crystalline compound $C_{19}H_{18}NO_4Br,AgNO_3$. Hydroberberine dibromide still has basic properties, for it forms a platinochloride, $(C_{20}H_{21}NO_4Br)_2,H_2PtCl_6$. When reduced with zinc and hydrochloric acid, it yields hydroberberine.

Various compounds of hydroberberine with ethyl iodide and bromide, and of these with gold and platinum chlorides, were prepared; these are tabulated below. Hydroberberine ethiodide, when treated with silver oxide, yielded an ethylammonium base, $C_{20}H_{21}NO_4Et{\cdot}OH + 4H_2O$, melting at 163—165°. When this is heated in a current of dry hydrogen, it loses not 4 but 5 mols. H_2O, ethylhydroberberine, $C_{20}H_{20}EtNO_4$, being presumably formed. This substance crystallises with $3H_2O$, when it melts at 240—245°; when dried at 100°, it loses $2H_2O$, leaving $C_{20}H_{20}EtNO_4 + H_2O$, or $C_{20}H_{20}NO_4,EtOH$. It also crystallises from a solution in chloroform and alcohol with $4H_2O$, and then loses $3H_2O$ when dried at 100, leaving the same compound as before. This substance is quite distinct from the ethyl base of hydroberberine from which it was prepared; it is not, as was to be expected, a tertiary base, but is a quaternary compound, and gives no alkaline reaction. With ethyl iodide, for example, it forms not an ethyl iodide additive compound, but a hydriodide from which a base cannot be set free by the action of potash. A number of halogen acid derivatives of ethylhydroberberine (tabulated below) were prepared for comparison with the corresponding ethyl halogen derivatives of hydroberberine.

Hydroberberine ethohydroxide,
$C_{20}H_{21}NO_4,EtOH + 4H_2O$,
m. p. 163—165°.

Hydroberberine ethochloride,
$C_{20}H_{21}NO_4,EtCl + 2\frac{1}{2}H_2O$,
m. p. 225—226°.

Hydroberberine ethaurochloride,
$C_{20}H_{21}NO_4,EtAuCl_4$,
m. p. 180—181°.

Hydroberberine ethoplatinochloride,
$(C_{20}H_{21}NO_4)_2,Et_2PtCl_6$,
m. p. 229—230°

Hydriodide of ethyl base,
$C_{20}H_{21}NO_4,EtI + H_2O$,
m. p. 227—228°.

Ethylhydroberberine,
$C_{20}H_{20}EtNO_4 + 4H_2O$,
m. p. 240—245°.

Ethylhydroberberine chloride,
$C_{20}H_{20}EtNO_4,HCl + 2\frac{1}{2}H_2O$,
m. p. 261—263°.

Ethylhydroberberine aurochloride,
$C_{20}H_{20}EtNO_4,HAuCl_4$,
m. p. 184—185°.

Ethylhydroberberine platinochloride,
$(C_{20}H_{20}EtNO_4)_2,H_2PtCl_6$,
m. p. 220—221°.

Hydriodide of ethylhydroberberine,
$C_{20}H_{20}EtNO_4,HI$,
m. p. 241—242°.

Hydrobromide of ethyl base, $C_{20}H_{21}NO_4,EtBr$, m. p. 250—251°.

Hydroberberine ethonitrate, $C_{20}H_{21}NO_4,EtNO_3 + H_2O$, m. p. 243—244°.

Hydrobromide of ethylhydroberberine, $C_{20}H_{20}EtNO_4,HBr$, m. p. 245—246°.

Ethylhydroberberine nitrate, $C_{20}H_{20}EtNO_4,HNO_3 + 2H_2O$, m. p. 131—132°.

It was further observed that, although an alcoholic solution of iodine oxidises hydroberberine to berberine hydriodide, it converts the hydroberberine ethylammonium base into hydroberberine ethiodide, and ethylhydroberberine into its hydriodide. C. F. B.

Lysine. By E. Drechsel and T. R. Krüger (*Ber.*, **25**, 2454—2457).—The platinochloride, $C_6H_{14}N_2O_2,H_2PtCl_6 + C_2H_6O$, obtained from caseïn, was dissolved in water, freed from alcohol by distillation, and from platinum by means of hydrogen sulphide, and the acid solution of the dihydrochloride thus obtained was heated on the water-bath with the calculated quantity of sulphuric acid until all the hydrochloric acid had been driven off. The residual syrup, which crystallised on cooling, was dissolved in hot water, the sulphuric acid accurately precipitated with barium hydroxide, and the solution filtered and evaporated to crystallisation. Not lysine, but lysine carbonate, or perhaps more properly, lysine lysinecarbamate, $2C_6H_{14}N_2O_2 + CO_2$, was obtained; this substance loses its carbonic anhydride when heated at 110° in a current of air freed from that gas.

If the dihydrochloride is evaporated to dryness on the water-bath with excess of milk of lime, and the residue distilled in a current of hydrogen, various basic products are obtained. In some experiments the aqueous portion of the distillate was treated with soda and benzoic chloride, and an oil obtained which crystallised on cooling to a substance which melts at 42·6°, and when boiled with water or alkalis or heated in hydrogen to 120°, yields benzoic acid and a substance apparently of a basic nature. C. F. B.

Constitution of Peptones. By P. Schützenberger (*Compt. rend.*, **115**, 208—213).—Blood fibrin from the horse was converted into peptone by the action of extractive pepsin in presence of hydrochloric acid. The solution has all the properties of proteïd peptone, and when evaporated in a dry vacuum it yields a yellowish friable mass of *fibrin-peptone*. When its solution is mixed with excess of ammonium sulphate, it yields a viscous precipitate as observed by Kühne.

During conversion into peptone, the fibrin combines with 3·97 per cent. of water; after drying in a vacuum, its composition, exclusive of the ash, is C, 49·18; H, 7·09; N, 16·33; O and S, 27·40. These numbers agree closely with those obtained by Kühne and Chittenden with carefully purified ampho-peptone from blood fibrin. The formation of fibrin-peptone may be represented by the equation $C_{56}H_{92}N_{16}O_{20} + 3H_2O = C_{56}H_{98}N_{16}O_{23}$.

When fibrin-peptone is heated for six hours at 150—180° with three times its weight of barium hydroxide, it yields ammoniacal nitrogen 4·1, carbonic anhydride 5·94, acetic acid 3·16, and solid re-

sidue 87·82 per cent., the sum of the products being practically identical in weight with the original peptone, a fact which seems to indicate that no combination with water takes place. The solid residue, exclusive of the ash, has the composition C, 47·52; H, 7·61; N, 12·93; O, 31·94; and the loss of carbon and nitrogen seems to be due to the formation of volatile bases of the pyrroline or pyridine groups, as observed in the case of other proteïds. The decomposition of the peptone may be represented by the equation $C_{56}H_{98}N_{16}O_{32} + 6H_2O = 2CO_2 + 4NH_3 + \frac{1}{2}C_2H_4O_2 + C_6H_7N + C_{47}H_{89}N_{11}O_{34}$. The ureides present in the fibrin remain in the fibrin peptone, and the decomposition of the latter in presence of baryta is similar to that of fibrin itself and other proteïds. C. H. B.

Molecular Weight of the Peptones. By G. Ciamician and C. U. Zanetti (*Gazzetta*, **22**, 449—452; compare Paal, this vol., p. 896).—The authors prepared pure peptone by dissolving the commercial substance in water, adding potassium ferrocyanide and acetic acid, and fractionally precipitating the solution with alcohol. The separated peptone was repeatedly (10 times) dissolved in water and precipitated by alcohol; it was finally dried over sulphuric acid.

Experiments made by the cryoscopic method in aqueous solutions on two samples of commercial peptone, after treating as above, gave the molecular weights as 529—555 and 317—344 respectively.

W. J. P.

Nucleïn. By H. Malfatti (*Zeit. physiol. Chem.*, **17**, 8—9; compare this vol., p. 224).—In a former paper the statement was made that nucleïc acid prepared from Liebermann's nucleïn can unite with guanine, forming a compound like the nucleïc acids obtained from natural nucleïn. Several repetitions of the experiments led, however, to negative results. W. D. H.

Pupin. By A. B. Griffiths (*Compt. rend.*, **115**, 320—321).—*Pupin*, $C_{14}H_{20}N_2O_5$, is a colourless, amorphous substance, obtained from the skin of the pupæ of various lepidoptera (*Pieris brassicæ*, *napi*, and *rapæ*, Latreille, and *Plusia gamma*, *Mamestra brassicæ*, and *Noctua pronuba*, Linn.), where it is secreted after the last change. The skins are boiled with aqueous soda, washed in succession with dilute acid, water, alcohol, and ether, and finally dissolved in strong hydrochloric acid. The crude product is precipitated by water and purified by repeated precipitation from acid solution.

Pupin dissolves in mineral acids, but not in neutral solvents. When boiled with strong mineral acids for a long time, it is hydrolysed to leucine and carbonic anhydride, each molecule yielding two of each of these substances. Jn. W.

Physiological Chemistry.

Air Vitiated by Respiration. By J. Haldane and J. L. Smith (*J. Pathol. and Bacteriol.*, **1**, 168—186).—From experiments on human beings the following conclusions are drawn:—

1. The immediate danger from breathing air highly vitiated by respiration arises entirely from the excess of carbonic anhydride and deficiency of oxygen, and not from any special poison. Experiments on animals, consisting of injecting the products of respiration into them (obtained by condensing the products of respiration expired into a Liebig's condenser), caused no more ill-effect than distilled water.

2. Excess of carbonic acid rather than deficiency of oxygen is the more potent cause of hyperpnœa and headache.

A practical conclusion drawn from these experiments is, that the unpleasantness of close rooms is due rather to the effect produced through the sense of smell; and, therefore, that personal cleanliness is more important than ventilation; in fact, the odours that arise may be removed by other means than the excessive ventilation now considered so necessary. W. D. H.

Formation of Sugar from Peptones in Blood. By R. Lépine (*Compt. rend.*, **115**, 304—305).—Purified commercial peptone (0·2 to 0·5 gram) is dissolved in the recent arterial blood (40 grams) of a healthy dog, defibrinated, or better, treated with sodium fluoride. In less than an hour the peptone is no longer to be recognised by the colorimetric reaction with copper sulphate, and the amount of sugar in the blood is found to have increased. With the temperature at 39°, or better, at 55—60°, peptone seems to yield nearly one-tenth of its weight of sugar. Jn. W.

Iron in the Fœtal Organism. By G. Bunge (*Zeit. physiol. Chem.*, **17**, 63—66).—In two former communications (Abstr., 1889, 789; this vol., p. 516) it has been shown that certain organs of the new-born mammal contain a store of iron, which is gradually used up in the formation of the iron-containing principles of the body, the milk containing insufficient iron for the purpose. In young guinea pigs this is not so marked, as very soon after birth their milk diet is supplemented by vegetable food rich in iron. Young cats, dogs, and rabbits, live longer on milk only. The rabbit is born blind, and otherwise immature, the guinea pig is covered with warm fur, and its eyes are open. One must, therefore, for fair comparison, examine the guinea pig in a condition corresponding to that of the new-born rabbit; that is, the fœtal guinea pig must be removed from the uterus. It is then found that the theory is fully confirmed; the guinea pig, like the rabbit, has the highest relative amount of iron in its body at the time of birth; the amount of iron is directly related to that in its food. W. D. H.

Iron in the Liver. By G. Bunge (*Zeit. physiol. Chem.*, **17**, 78—82).—In order to estimate the iron in the liver it is, above all things, necessary to have it blood free. This can only be done during life; salt solution being passed through a cannula into the portal system in anæsthetised animals; the fluid is allowed to escape by the hepatic artery and vena cava inferior. The liver is removed and weighed, but only those portions which are perfectly pale, and give no red colour after soaking in distilled water, are taken for iron analyses. The amount of iron in milligrams per 100 grams of liver in 10 analyses (dogs and cats) were, 8·7, 1·0, 2·5, 2·6, 4·7, 4·7, 35·5, 5·2, 7·0, 6·4. The high number, 35·5, was in a very young animal, and contrasts forcibly with the rest, which were full grown. Investigations in the same direction with other organs are in progress.

W. D. H.

Horse Fat. By C. Amthor and J. Zink (*Zeit. anal. Chem.*, **31**, 381—383).—See this vol., p. 1533.

Myristic Acid in Ox Gall. By Lassar-Cohn (*Zeit. physiol. Chem.*, **17**, 67—77).—Myristic acid is obtained by fractional precipitation with barium acetate from the acids of ox bile. The percentage is 0·004. This acid has been hitherto found in eight plants, and in spermaceti. Whether it occurs in ordinary fat in small quantities is now under investigation. W. D. H.

Influence of Hot Baths on the Excretion of Nitrogen and Uric Acid from the Human System. By E. Formanek (*Monatsh.*, **13**, 467—481).—A single hot air or vapour bath does not cause any perceptible change in the excretion of nitrogen from the system, but if baths be taken on two consecutive days, the excretion of nitrogen is found to increase on the second day, the increase continuing until the day following. The same thing holds also for the excretion of uric acid. A temporary raising of the temperature of the body is, apparently, therefore, of little effect in this respect, it being necessary to maintain the action for some time before change is noticed.

H. C.

The Excretion of Nitrogen in Urine. By G. Gumlich (*Zeit. physiol. Chem.*, **17**, 10—14).—Analytical data of a large number of experiments with urine are given in tables or expressed in curves. The points investigated were, (1) the total nitrogen; (2) the nitrogen in ammonia; (3) the nitrogen left after precipitating by phosphotungstic acid; (4) the nitrogen of the so-called "extractives," that is, (1) − (2 + 3).

With different diets, there were found:—

1. A relatively large increase and diminution of urea with meat and vegetable food respectively.

2. A relative increase of ammonia with vegetable food. There was no change with animal food only.

3. A large relative diminution and increase of extractives with meat and vegetable diet respectively.

A large number of morbid urines were also examined. In febrile disorders there was a relative lessening of urea, an increase of ex-

tractives and of ammonia. In diabetes, all cases showed a relatively high percentage of ammonia; the amount of extractives and urea, as in healthy persons, varied with the diet.

In cases of liver cirrhosis, severe anæmia, and heart failure, there was relative lessening of urea, and increase of ammonia and extractives.

In cases of kidney disease, there was a lessening of total nitrogen, and an absolute and relative increase of ammonia. In uræmia, the urea excreted varies but little, but the extractives almost disappear: these substances appear to be retained in the tissues. The urea excreted in kidney disease is relatively great.

In healthy and sick persons, the excretion of extractives is increased if the body weight falls. It appears that the katabolism of tissue elements yields more extractives relatively than the decomposition of nitrogenous food stuffs. W. D. H.

Reducing Agents in Normal Human Urine. By G. S. Johnson (*Chem. News*, **66**, 91).—In correcting a misquotation in Neubauer and Vogel's *Analyse des Harns*, p. 57, the author points out that, when removing reducing substances from urine by means of mercuric chloride, he disposes of the excess of mercury by adding ammonia solution cautiously until precipitation is complete; under these circumstances both the solution, and the precipitate when decomposed by hydrogen sulphide under water, are free from substances reducing copper oxide. He recognises that when hydrogen sulphide is used to remove the excess of mercury, a decidedly reducing solution is produced. D. A. L.

Occurrence of Acetyl Derivatives in the Urine of Animals after Ingestion of Aldehydes. By R. Cohn (*Ber.*, **25**, 2457—2470).—Some time since (Jaffé and Cohn, Abstr., 1887, 1032) it was discovered that when dogs or rabbits are fed with furfuraldehyde, a Perkin's synthesis takes place, the furfuraldehyde condensing with acetic acid to form furfuracrylic acid, which leaves the body in combination with glycocine, occurring as furfuracryluric acid in the urine. Attempts to discover analogous syntheses have failed. Benzaldehyde is not converted into cinnamic acid; indeed, the latter substance, if introduced into the organism, leaves it as benzaldehyde. Thiophenaldehyde, administered to a dog, left the system as thiophenuric acid, partly as such, and partly in combination with carbamide. No thienylacrylic acid was found; and indeed this substance, when administered to a rabbit, was found to undergo decomposition, leaving the organism as thiophenuric acid. Further, in the cases of acetaldehyde, paraldehyde, chloral hydrate, and vanillin, no condensation with acetic acid was observed.

In some further experiments, however, with the nitrobenzaldehydes, it was found that acetic acid does play a part in the reaction, forming acetamido-derivatives.

When a dog is fed with metanitrobenzaldehyde, the latter is converted into metanitrohippuric acid, and leaves the organism partly as such, partly in combination with carbamide. If, however, rabbits

are experimented on, in addition to metanitrobenzoic and metanitrohippuric acids, metacetamidobenzoic acid is found in the urine. If metamidobenzoic acid is administered, no metacetamidobenzoic acid is formed, but uramidobenzoic acid.

Orthonitrobenzaldehyde, administered to rabbits, is for the greater part destroyed; a small quantity is converted into orthonitrobenzoic acid.

When paranitrobenzaldehyde is administered, a substance of the composition $C_{16}H_{14}N_2O_7$ makes its appearance in the urine. This substance forms colourless, spherical aggregates of small needles, fantastically disposed at the edges; it is rather insoluble in ether, soluble in boiling alcohol, and very slightly soluble in boiling water. It possibly has the constitution $COOH{\cdot}C_6H_4{\cdot}NO_2,NHAc{\cdot}C_6H_4{\cdot}COOH$, being a molecular compound of paranitrobenzoic and paracetamidobenzoic acids. When distilled, it gives off acetic acid; if heated at 150° in a sealed tube with hydrochloric acid, or when boiled with hydrochloric acid or barium hydroxide, it yields paranitrobenzoic acid; whilst reduction with ferrous hydroxide converts it into paracetamidobenzoic and paramidobenzoic acids. It can be synthesised by mixing hot solutions of paranitro- and paracetamido-benzoic acids, but is not formed by the loss of a molecule of water between these, for in that case the formula $C_{16}H_{14}N_2O_7$ would require the presence of 1 mol. of water of crystallisation, whereas it loses no water when heated at 150°, although it volatilises to some extent. In solution, it dissociates; the solution giving a lowering of the freezing point corresponding to a mixture of its two constituents. The solid substance is not, however, a mere mixture, but a true chemical compound, and that for the following reasons. It is formed when solutions of its two constituents are mixed, in proportions of either 1 : 2, 1 : 1, or 2 : 1; it cannot be separated into its constituents by fractional crystallisation, and when its silver salt is precipitated in three successive fractions, the third fraction contains the same percentage of silver as the first. It is a molecular compound of a novel and interesting type. Probably the two molecules are united by their nitrogen atoms. C. F. B.

Sulphates and Ethereal Hydrogen Sulphates in the Urine during Diarrhœa. By S. T. Bartoschewitsch (*Zeit. physiol. Chem.*, **17**, 35—57).—Full analytical details support the following conclusions:—The absolute and relative quantity of the preformed sulphates (a) and the ethereal hydrogen sulphates (b) are smaller during diarrhœa than normal, but the fractions $\frac{a+b}{b}$ or $\frac{a}{b}$ are smaller.

In calomel diarrhœa, the disinfection produced by the drug lessens b; this is not true for all purgatives, as castor oil increases b and lessens the fraction $\frac{a+b}{b}$. From this it appears that there are two classes of purgatives, those which disinfect the intestines and those which do not.

The diagnostic importance of such observations is not great, except that careful experimentation might sometimes lead to the detection of

those cases of malingering when diarrhœa has been artificially produced. W. D. H.

Hæmatoporphyrinuria. By A. E. Garrod (*J. Pathol. and Bacteriol.*, **1**, 187—197).—Small quantities of hæmatoporphyrin are present in healthy urine. Increase occurs in many diseases: some infective, others (as many cases of liver disease) not so. Anæmia does not constantly increase the amount, and in febrile diseases, the amount is not proportional to the severity of the attack.

W. D. H.

Physiological Action of Pentoses. By W Ebstein (*Virchow's Archiv*, **129**, 401—412).—In view of the dieting of diabetic patients, it is necessary to investigate the physiological action of various forms of sugar; and the present research relates to the two pentaglucoses or pentoses ($C_5H_{10}O_5$), xylose and arabinose.

These substances reduce Fehling's solution, Nylander's reagent, and form osazones with phenylhydrazine. They also give the following characteristic reactions:—(1.) By distillation with hydrochloric acid they yield furfuraldehyde. (2.) A solution mixed with an equal volume of concentrated hydrochloric acid and then with a solution of phloroglucinol in equal parts of hydrochloric acid and water, and warmed, gives a beautiful red colour, which gives a dark absorption band to the right of the D line. Most urines give a deep colour with these reagents, but the characteristic absorption band is not shown.

Xylose, dissolved in water or coffee, or in the solid state mixed with the food, was given to various people. The amount in the urine was estimated by Fehling's solution (1 milligram xylose = 1·9 milligrams copper), after any glucose that might have been present had been removed by fermentation with yeast. It appears that xylose is not assimilated, even when taken in very small quantity, and it can be recognised in the urine within an hour or two after the administration of 0·5 gram. This is true both for healthy and diabetic persons. One received 25 grams of xylose; in the next 24 hours 9·5 grams were found in the urine, and the excretion continued for the two following days.

Arabinose (1 milligram = 1·95 milligrams copper) gave practically the same results.

The use of fruit, such as pears, that contain pentosanes, the mother substances of pentoses, may give the characteristic tests for pentoses in the urine. It is, of course, important not to confound such a temporary condition with diabetes. W. D. H.

Pharmacological Investigations of Ketones and Acetoximes. By H. Paschkis and F. Obermayer (*Monatsh.*, **13**, 451—466).—In their physiological effects, the ketones of the fatty series resemble the alcohols, producing narcosis and decrease of blood pressure. In strength of action, the different ketones are by no means equal, this property being chiefly determined by the nature of the alkyl groups present in the molecule. In the case of the acetoximes, it was at first supposed that these would probably decompose in the

system with separation of hydroxylamine. Their effect, however, is found to be totally different from that of hydroxylamine and to be generally similar to that of the alcohols and ketones. Their strength of action, as in the case of the ketones, depends on the nature of the alkyl groups which they contain, and it may be said generally that the conversion of a ketone into the acetoxime does not cause any marked change in its physiological action.

H. C.

Physiological Action of Sulphonal. By W. J. Smith (*Zeit. physiol. Chem.*, **17**, 1—7).—Large doses of sulphonal do not influence the excretion of urinary nitrogen. There is also no effect on the sulphuric acid. Kast (*Berlin. klin. Woch.*, 1888, No. 16) states that the greater part of the sulphonal given does not enter the urine unchanged, but as a readily soluble organic sulphur compound. It was found, however, in the present research, that in dogs, after 3-gram doses in solution, small quantities of unchanged sulphonal passed into the urine. Jaffé (*Deutsch. med. Woch.*, 1891, No. 21) and Jolles (*Pharm. Post*, 1891, No. 52) have also found the same in human urine.

What are the compounds in which the greater part of the sulphonal passes into the urine? There are two possibilities: it is either *ethylsulphonic acid*, formed from the easily oxidisable ethylsulphinic acid ($HSO_2 \cdot C_2H_5$); or *sulphoacetic acid* ($SO_3H \cdot CH_2 \cdot COOH$). In order to settle the matter, these two compounds were given to dogs and men, and the urine examined.

After doses of 6 grams of potassium ethylsulphonate, the sulphuric acid was not increased, and the salt given was separated from the urine, although in too impure a form for analysis.

The same dose of sodium sulphoacetate lessened rather than increased the urinary sulphuric acid, although the total sulphur in the urine was double, showing that the salt had been absorbed. The barium salt was crystallised from the urine. In urine, after the use of sulphonal, however, no trace of barium sulphoacetate was obtainable; the chief end product of the sulphonal thus appears to be ethylsulphonic acid.

W. D. H.

Toxic Action of Carbon Bisulphide. By A. Westberg (*Zeit. anal. Chem.*, **31**, 484—486).—See this vol., p. 1520.

Chemistry of Vegetable Physiology and Agriculture.

To what extent is Atmospheric Nitrogen Assimilable? By B. Frank (*Ann. Agron.*, **18**, 414—416; from *Deut. landw. Presse*, 1891, 779).—The results of a new series of pot cultures, in which leguminous and other plants were grown, with and without nitrogenous manures, and with and without inoculation of the soil with the nodules of symbiosis in the case of the leguminous plants, may be summed up thus:—When the organism of symbiosis is absent, yellow

lupins and peas may still develop completely if supplied with nitrogenous manure, but, under the influence of symbiosis alone, better development is attained than with the nitrogenous manure in the absence of symbiosis. In the presence of symbiosis, nitrogenous manure seems even injurious to the yellow lupin, but the pea profits by an addition of nitrogenous manure, even when symbiotic growth takes place.

It has been shown that peas and yellow lupins may, in good soil, directly assimilate atmospheric nitrogen without any development of tubercles; this assimilation of nitrogen, however, is inferior to what takes place in poor soils almost entirely under the influence of symbiotic growth. Peas assimilate considerable quantities of atmospheric nitrogen in good soils, and symbiosis increases this faculty. Clover behaves like peas.

Not only does Frank hold that these leguminous plants *may* assimilate free nitrogen without the development of any root tubercles, but he has also obtained fixation of nitrogen, although to a less extent, with cultures of oats, buckwheat, spinney, asparagus, and colza, which never show any development of root nodules. J. M. H. M.

Fixation of Free Nitrogen during Vegetation. By E. Breal (*Ann. Agron.*, **18**, 369—379).—The author has grown plants of cress in river sand, watered with a solution of potassium chloride with calcium phosphate in suspension and a little added magnesium sulphate, under conditions which demonstrate the fixation of atmospheric nitrogen by the combination. A growth of four months in 6·3 kilos. of the soil showed gains of nitrogen in the aërial parts of the plants of 0·305 and 0·290 gram, and in the soil and roots of each pot of 0·339 gram N. The seeds of the plants grown in this way were lighter, and contained less nitrogenous matter than the seeds sown, which, of course, had been grown in a nitrogenous soil.

J. M. H. M.

Sodium as a Plant Food. By A. Atterberg (*Expt. Stat. Record*, **3**, 554; from *Deut. landw. Presse*, 1891, 1035).—In the author's experiments, black Tartar oats were grown in quartz sand and watered with nutritive solutions containing hydrogen potassium phosphate, magnesium sulphate, and potassium, sodium, and calcium nitrates. Different amounts of potassium were replaced by equivalent amounts of sodium and of calcium respectively. The results show a falling off in the yield of oats when the supply of potassium was diminished, but the falling off was much less in the sodium series than in the calcium series. Thus, with 9·42 grams of potassium, the sodium series gave 141, and the calcium series 142, grams of oats; with 5·65 grams of potassium, the sodium series gave 134, the calcium series 112 grams of oats; with 1·88 grams of potassium, the yields were 112 and 75 grams respectively. Sodium may thus be of great importance where potassium is deficient, and the large amount of sodium in many of the Stassfurt salts is no longer to be considered as useless. N. H. M.

Distribution and Condition of Iron in Barley. By P. Petit (*Compt. rend.*, **115**, 246—248).—When barley is treated repeatedly with a dilute solution of hydrochloric acid in alcohol, only a minute quantity of iron is dissolved, and it follows that practically the whole of the iron is present in the form of nucleïn. An investigation of the distribution of the iron in various parts of the grain shows that the dry embryon contains 0·11 per cent., the integument 0·097, and the proteïds 0·002 per cent.

During germination, the quantity of iron present in the form of nucleïn varies but little, although the proportion of iron diminishes. In the early stages of germination, the iron in the embryon is sufficient for the requirements of the plant, and none is withdrawn from the integument or the proteïds. C. H. B.

Oil of Cinnamon. By J. Weber (*Arch. Pharm.*, **230**, 232—248).—The author has examined the oil from the leaves of *Cinnamomum ceylanicum*, Breyn., and substantially confirms the results of Stenhouse (*Annalen*, **95**, 103) and Schaer (Abstr., 1882, 1300). The oil was obtained through Schuchardt, of Görlitz, from Port Louis, Seychelles Islands, and was guaranteed pure. It had the colour and odour of oil of cloves and a burning taste; its sp. gr. was 1·0552 at 18·5°. For the most part it consisted of eugenol, but contained, in addition, small quantities of cinnamaldehyde and of terpenes. Attempts to identify pinene and cineole among the latter were unsuccessful. Benzoic acid, also, could not be detected.

Another oil was examined, purporting to be obtained from the roots of the same plant, and procured from Schimmel, of Leipsic. Since the completion of the research, however, this firm have thrown doubts on the genuineness of this oil, suspecting it to be derived from the leaves. It had the colour and odour of oil of cloves, and its sp. gr. at 19° was 1·0411. This oil also consisted mainly of eugenol, but contained also safrole, small quantities of benzaldehyde, and a considerably larger amount of terpenes than the first oil examined.

C. F. B.

A Crystalline Constituent of Genipa brasiliensis, Mart. By W. Kwasnik (*Chem. Zeit.*, **16**, 109—110).—The fresh, crushed leaves are extracted three times with alcohol (sp. gr. 0·815) at 60°, the extract filtered, and the alcohol distilled completely. The residue is extracted with hot water, the solution filtered, and lead acetate added to the filtrate so long as it produces a precipitate. Another filtration and a similar treatment with tribasic lead acetate follow, and the solution is then treated with hydrogen sulphide to remove excess of lead, and evaporated to a syrup; this crystallises on cooling, and the crystals are purified by trituration with absolute alcohol and recrystallisation therefrom. Water may be substituted for alcohol in this prescription, but the yield (0·3 per cent.) is not so good. By the alcohol treatment, 0·54 per cent. was obtained from the fresh leaves, and 0·79 per cent. from the fresh bark.

The crystals are colourless, slender, sweet needles, and are insoluble in ether, light petroleum, benzene, cold alcohol, and amyl alcohol, but dissolve in water, chloroform, aniline, boiling alcohol, and acidified

amyl alcohol. The substance melts at 165°, and does not behave as a glucoside. Its empirical formula is $C_3H_7O_3$, which, together with the above properties, indicates that it is identical with mannitol. Its aqueous solution is optically inactive, except when alkalis or boric acid are present, and reduces Fehling's solution slightly after boiling or long standing. These properties are also shared by mannitol, although it is generally stated that this sugar does not reduce Fehling's solution; this may be true of it *quâ* mannitol, but an alteration product is evidently formed when it is heated with alkalis. This matter is being investigated. A. G. B.

Chemical Study of the Cotton Plant. Feeding Value of the Cotton Plant and its Parts. By J. B. McBryde (*Expt. Stat. Record*, **3**, 537—542; from *Tennessee Stat. Bull.*, **4**, 120—125, and 141—145). —The first paper includes analyses of the whole plant and of its parts, a determination of the relative weight of the different parts of the plant, and a comparison of the fertilising constituents in 1 acre of cotton (300 lbs. of lint), of corn (20 bushels), and of oats (30 bushels of grain). In the second paper, analyses with reference to food constituents are given, and the composition of the plant after picking, compared with that of oats. Analyses of the parts of cotton seed are also given.

The first table shows the percentage composition of the substances dried at 100°.

	Whole plant.	Lint.	Seed.	Bolls.	Leaves.	Stems.	Roots.
Crude ash	6·27	1·77	3·53	8·33	15·93	4·54	3·60

Stems. 2	4·10	34·35	2·14	14·72	7·10	1·95	4·11
Roots. 1	5·10	26·00	4·88	21·04	10·16	3·82	6·19
Roots. 2	4·02	39·94	3·97	11·49	8·97	2·97	6·92

In the second table, the composition of the ash of the whole plant, and of the various parts of the plant grown in (1) 1889 and (2) 1890, are given. N. H. M.

Composition of the Ramie Plant (Boehmeria). By M. E. JAFFA (*Expt. Stat. Record*, **3**, 371—373; from *California Stat. Bull.*, **94**, 1—6).—Separate analyses were made (I) of the entire plant, (II) stalks, (III) bark, and (IV) leaves. The following percentage amounts of dry matter, ash, and nitrogen were found in the fresh substance:—

	Dry matter.	Ash.	Nitrogen.
Whole plant	18·74	1·49	0·258
Stalks (without bark).....	18·25	0·57	0·146
Bark (with fibre and gum) ..	19·09	0·31	0·210
Leaves	19·35	3·81	0·481

The percentage composition of the ash of the whole plant and its parts was:—

	K_2O.	Na_2O.	CaO.	MgO.	Fe_2O_3, Al_2O_3.	MnO.	P_2O_5.	SO_3.	SiO_2.	Cl.
I.	11·82	2·35	30·87	7·89	2·41	0·17	7·29	2·26	33·01	2·43
II.	37·79	8·15	17·32	10·58	2·95	0·35	16·38	3·46	1·56	1·87
III.	32·58	8·77	22·28	11·64	0·84	0·18	12·64	3·68	5·24	2·75
IV.	4·18	0·54	34·74	7·02	2·35	0·12	4·72	1·88	42·42	2·55

A good soil will yield about 10 tons of dried stalks and 4·25 tons of leaves per acre per annum, and thus remove about 658 lbs. of lime, 252 lbs. of potash, 156 lbs. of phosphoric acid, and 370 lbs. of nitrogen per acre. The bark and fibre, however, which is all that is wanted, contain less than 10 per cent. of the potash, 3 per cent. of the lime, 7 per cent. of the phosphoric acid, and 15 per cent. of the total nitrogen, so that the loss will be comparatively small if the leaves and stalks are returned to the soil. N. H. M.

Analysis of California Oranges and Lemons. By G. E. COLBY and H. L. DYER (*Expt. Stat. Record*, **3**, 78—81; from *California Stat. Bull.*, **93**, 1891).—The original paper gives analyses of 23 samples of oranges and 4 of lemons. The average percentage composition of the pure ash of the oranges and lemons, which amounted to 0·432 and 0·526 per cent. respectively in the fresh fruit, is as follows:—

	K_2O.	Na_2O.	CaO.	MgO.	Fe_2O_3 and Al_2O_3.	MnO_2.
Oranges..	48·94	2·50	22·71	5·34	0·97	0·37
Lemons ..	48·26	1·76	29·87	4·40	0·43	0·28

	P_2O_5.	SO_3.	SiO_2.	Cl.
Oranges....	12·37	5·25	0·65	0·92
Lemons	11·09	2·84	0·66	0·39

N. H. M.

Food Value of Brushwood. By A. STUTZER (*Expl. Stat. Record*, **3**, 493; from *Deut. landw. Presse*, 1891, 943).—It has been proposed

to use the younger twigs from trimming out the tops of trees to supplement the food supply when crops are poor. It has to be broken up, malt (1 per cent.) added, and the whole treated with hot distillery liquid, and kept for 1—3 days. Samples so prepared from various kinds of wood had the following percentage composition:—

	Water.	Crude proteïn.	Amides and digestible proteïds.	Undigestible proteïn.	Coefficient of digestibility of crude proteïn.
Beach....	10·12	4·50	1·25	3·25	27·80
Pine	7·51	5·19	2·13	3·06	40·90
Alder....	6·87	7·12	3·56	3·56	50·00
Locust...	6·98	7·94	5·06	2·88	63·80

N. H. M.

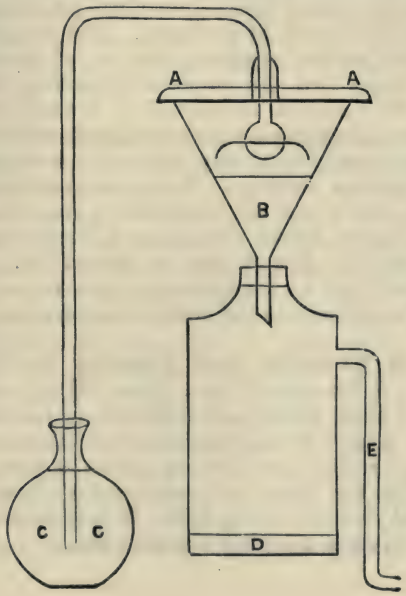
Composition of Frozen and Unfrozen Beet-chips. By A. Stutzer (*Expt. Stat. Record*, **3**, 498; from *Deut. landw. Presse*, 1891, 943).—Samples of unfrozen and of severely frozen sugar-beet diffusion chips, taken from the same silo, contained respectively 90·4 per cent. of water and 0·6 per cent of ash, and 87·5 per cent. of water and 1·2 per cent. of ash. The percentage composition of the dried materials freed from ash was as follows:—

	Crude fat.	Crude proteïn.	Crude cellulose.	Nitrogen-free extract.	Acid.
Unfrozen	0·77	12·06	28·90	56·96	1·31
Frozen.....	1·35	10·45	18·19	65·44	4·57

The coefficient of digestibility of the proteïn was: unfrozen chips, 86·3 per cent.; frozen chips, 70 per cent. The freezing made a part of the cellulose more digestible, increased the acid, diminished the digestibility of the proteïds, and gave rise to greater losses of organic matter when kept. To prevent loss, the chips should be dried at the factory before being disposed of to farmers.

N. H. M.

New Experiments on Soil Inoculation. By Schmitter (*Expt. Stat. Record*, **3**, 491; from *Wochenschr. pomm. ökon. Ges.*, 1891, 251; compare *Bied. Centr.*, **19**, 393).—Three plots of land (size not given) which had remained long uncultivated and were free from leguminous growth, were each divided into two parts, and half of each manured with superphosphate and potassium and magnesium sulphates. The plots were then divided crosswise into eight strips (1 m. wide), being separated from each other by intervening strips, and sown with yellow lupins. Strips 2, 4, 6, and 8 of each plot were treated with fresh lupin soil (1800 lbs. to 9 tons per acre). For two months, the growth was rather weak on all the plots, but afterwards became more luxuriant. On plots 1 and 2, the growth seemed equal on all the strips up to harvest time. On plot 3, the growth remained equal on all the strips until about the middle of July, when the inoculated strips began to gain; and it was found, at the time of taking up, that the roots of the plants in these plots had more and better-developed nodules than those of the plots which were not inoculated; the length of root and the growth generally were also increased by the inoculation. In the case of plots 1 and 2, the inoculation was without effect, the number of nodules averaging the same for all the strips. The total yield of hay



from the inoculated strips (of plot 3) was 19·188 kilos., that of the uninoculated strips 16·400 kilos.; the yields of seeds were respectively 11·200 and 10·100 kilos. N. H. M.

Inorganic Acid Substance in Soils. By P. de Mondesir (*Compt. rend.* **115**, 316—318).—A considerable proportion of the lime in soils is not combined with carbonic acid or other ordinary acid, as the amount extracted by dilute hydrochloric or nitric acids is in excess of that required to saturate the carbonic, phosphoric acids, &c., removed at the same time. The extracted soil, moreover, is still acid in reaction after washing with water, and is capable of taking up an amount of lime corresponding with the excess. The acid substance, the amount of which varies from 0·2 to 1 per cent. by weight of the soil, is not organic, for it withstands the action of moderately hot permanganate or incineration at a dull red heat, and it is not free silica, as its acid properties are not destroyed by heating for several hours at 160—170°. It resides chiefly in the clay, but not entirely, as a considerable proportion remains adhering to the sand after the clay has been separated. Neither sandstone nor kaolin shows this acidity, and colloïdal clay shows only a trace. The substance is probably an argillaceous silicate, but its nature is at present under investigation.

Jn. W.

Analytical Chemistry.

Apparatus for Washing Precipitates. By M. Forbes (*Chem. News*, **66**, 55).—The filtering funnel B is furnished with a tight-

fitting cover made of a lead and a rubber disc, A, with a bulb tube passing through the centre, and held in position by a piece of rubber tubing passing over a tubular projection on the lead disc; a long tube dipping over into the washing liquid, C, is also attached to this piece of tubing. When a precipitate is collected in the funnel, and the filter pump started, the cover, &c., are adjusted, and a steady stream of the washing liquid issues from four small holes pierced through the side of the bulb. D. A. L.

A New Combustion Furnace. By F. Fuchs (*Ber.*, **25**, 2723—2725).—The furnace, which is described with the aid of drawings, combines in principle Erlenmeyer and Babo's and Glaser's systems; the author claims to have accomplished this in such a manner that whilst the advantages of each are retained, their disadvantages are excluded. A. R. L.

Iodometry. By T. Salzer (*Zeit. anal. Chem.*, **31**, 376—381).—The author, whilst admitting with Topf (Abstr., 1887, 688) that the addition of ammonium carbonate to thiosulphate solution alters its relation to iodine, maintains that the addition has a marked effect in preserving the strength of the solution unchanged. A solution to which 2 grams of ammonium carbonate per litre had been added, proved, after keeping for five years without special precautions, to be of exactly the same strength as one freshly made without ammonia from the same specimen of thiosulphate. On the other hand, a new solution containing carbonate required a larger quantity of iodine to give a yellow colour, and this colour was not permanent until 20 per cent. more iodine had gradually been added. The addition of starch seems to prevent the disappearance of the excess of iodine, and the failure of Mohr to notice these anomalies probably arose from his use of strongly acid starch as indicator. The subject still needs investigation. The author advocates the use of chemically pure thiosulphate, and shows that the methods of testing employed by Topf (Abstr., 1887, 997) are not trustworthy. Owing to the solubility of barium sulphate and carbonate in thiosulphate solution, 2 per cent. of sodium sulphate or carbonate may be present without producing any turbidity with barium chloride. It is necessary first to oxidise the thiosulphate (together with any unsaturated sulphur salts) by a small excess of pure iodine before testing with barium nitrate. Calcium sulphide and chloride should also be looked for. A solution made from the pure salt may be accepted as a standard as long as it gives (after addition of iodine) no turbidity with barium nitrate.

M. J. S.

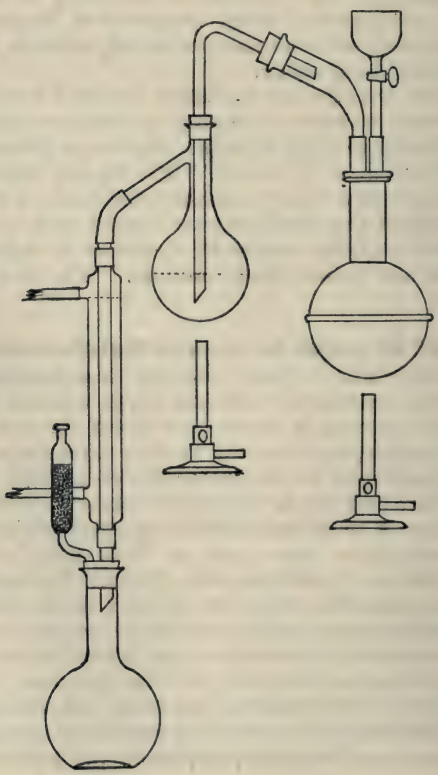
Detection of Chlorine and Bromine in the presence of Iodine. By D. S. Macnair (*Chem. News*, **66**, 5).—The freshly precipitated silver iodide, bromide, or chloride, or the mixture of any or all of them, is heated with potassium dichromate and concentrated sulphuric acid; by this operation the iodide is completely converted into iodate, whilst the other two salts evolve chlorine and bromine respectively, and yield silver sulphate. It only remains to identify the gas or gases evolved to complete the detection. D. A. L.

Volumetric Estimation of Soluble Sulphides. By D. Vitali (*L'Orosi*, **15**, 109—112).—This method depends on the complete precipitation of the sulphur in neutral solutions of normal sulphides by some heavy metal, phenolphthaleïn being used as an indicator to mark the finish. The solution must be free from carbonates, otherwise the carbonic anhydride must be removed by means of a soluble barium salt before proceeding; a few drops of an alcoholic solution of phenolphthaleïn are then added, and a decinormal solution of zinc acetate run in until the liquid is decolorised. Hydrosulphides may be indirectly estimated by boiling their solutions for a little while and determining the amount of normal sulphide left. In solutions containing free hydrogen sulphide, hydrosulphides, and normal sulphides, the total hydrogen sulphide may be found by titration with iodine, the solution boiled, and the normal sulphides estimated by titration with zinc acetate. If thiosulphates are also present, the amount of these must be determined in a separate portion, from which the whole of the hydrosulphide has been precipitated.

S. B. A. A.

Volumetric Estimation of Combined Sulphuric Acid. By K. Farnsteiner (*Chem. Zeit.*, **16**, 182).—The following process, originally recommended by Volhard, is, according to the author, not suitable for the estimation of large quantities of sulphuric acid, but may be recommended for the estimation of sulphates in common soda, potash, salt, and drinking water.

The hot solution, which must be faintly acidified with hydrochloric acid, is mixed with a known quantity of barium chloride. After adding pure ammonia to faint alkaline reaction, a known quantity of pure potassium chromate is added. The liquid, which should be strongly yellow, is allowed to cool, and then made up to a definite volume. One half of the liquid is now filtered, and, after acidifying with hydrochloric acid, the excess of chromate is estimated by the potassium iodide and thiosulphate method. The test analyses are satisfactory.



L. de K.

Estimation of Nitrogen in Organic Substances. By F. Blau (*Monatsh.*, **13**, 277—285).—The following modification of Dumas' method for the estimation of nitrogen gives a much smaller error than the original process, is more convenient for use with volatile substances and liquids, and has the further advantage of requiring only one combustion tube for a number of determinations, which can consequently be carried on in rapid succession:—The substance in which the nitrogen is to be estimated is weighed out in a small boat, placed in a combustion tube open at both ends, and gradually carbonised in a stream of carbonic anhydride. The vapours evolved are led through coarsely powdered copper oxide, the remaining carbonaceous matter is burnt in a current of oxygen, and the excess of the latter is absorbed by heated copper, which is also contained in the tube. Any nitrogen remaining in the apparatus is driven into the measuring vessel by a stream of carbonic anhydride. The apparatus is designed in such a way that oxygen and carbonic anhydride, free from nitrogen, can be passed, at pleasure, along the combustion

tube. The oxygen may be conveniently prepared by allowing commercial hydrogen peroxide (3—5 per cent.), which has been previously acidified with dilute sulphuric acid (15 per cent.), to fall on crystals of potassium dichromate contained in a specially arranged vessel. G. T. M.

Estimation of Nitrogen in Organic Substances. By W. F. K. Stock (*Analyst*, **17**, 109—112, 152—153).—The process to be described must not be considered to be a mere modification of Kjeldahl's method. In the latter process, the substance is oxidised, and its nitrogen converted into ammonia, by the sole action of boiling sulphuric acid, and only in the last stage a little potassium permanganate is added, and even this addition is not advisable. The author oxidises the substance with a mixture of sulphuric acid and manganic dioxide, and so succeeds in completely converting its nitrogen into ammonia.

From $\frac{1}{2}$ to 1 gram of the substance is mixed in a conical flask or small beaker with 10 c.c. of sulphuric acid (sp. gr. 1·84) and 5 grams of pyrolusite, which should be fine enough, but yet not too fine. The flask is heated until the contents assume a dark-green colour, which

indicates the end of the reaction. After cooling, water is added, and the contents transferred to the apparatus. An excess of sodium hydroxide is added, and the ammonia is distilled off and titrated in the usual way.

The apparatus, shown in the accompanying figure, consists of a copper boiler of 600 c.c. capacity, closed by a screw cap and india-rubber washer. This cap carries a tapped funnel for the introduction of the soda solution, and a wide evolution tube to serve as a reflux tube, in case of sudden frothing. The tube is closed by an indiarubber stopper carrying a tube bent at such an angle as to permit of its passing down the centre of a Wurtz flask, which serves as a washing flask for the vapours from the copper boiler. Both boiler and flask are provided with burners, and both must be kept boiling throughout the experiment. The Wurtz flask is in turn connected with a 14-in. Liebig's condenser, set vertically, and this terminates in a 500 c.c. receiving flask, fitted with a guard tube filled with beads, through which the standard acid is run into the receiver. The open ends of the tubes are all ground off at an acute angle, so as to prevent the formation of piston drops.

The object of the Wurtz flask is to prevent any sodium hydroxide from getting into the standard acid, and addition of zinc is quite unnecessary when using the apparatus.

In Kjeldahl's original process the oxidation generally lasts an hour; by the author's method the nitrogen is fully converted into ammonia in a few minutes.

If the substance contains chlorine, it should be first heated for some time with sulphuric acid alone before adding the manganic dioxide.

To prove the accuracy of the process, the author communicates some very successful experiments with ammonium chloride, ammonium oxalate, and potassium ferrocyanide; also experiments with bone-meal, cotton cake, and fish flesh, the nitrogen of which had been previously estimated by a soda-lime combustion. L. DE K.

Boyer's Method of Estimating Nitrogen. By C. ARNOLD and K. WEDEMEYER (*Zeit. anal. Chem.*, **31**, 388—389).—The authors have tested Boyer's method (this vol., p. 237) with various nitrates. The results showed no constant relation whatever to the calculated percentages, and no modification of the method, or of those of Ruffle and Tamm-Guyard, gave any better numbers. M. J. S.

Estimation of Nitrogen in Nitrates. By C. ARNOLD and K. WEDEMEYER (*Zeit. anal. Chem.*, **31**, 389—392).—The total nitrogen in a great variety of organic and inorganic nitrates is completely converted into ammonia by heating with a mixture of equal parts of sodium formate, soda-lime, and crystallised sodium thiosulphate with 2 parts of dehydrated thiosulphate. The operation is performed in a combustion tube 45 cm. long and 10—12 mm. bore. There is first introduced 5 cm. of a mixture of 1 part of sodium formate with 9 parts of soda-lime, then the substance with the above mixture, occupying 25—28 cm., then 10 cm. of the mixture of soda-lime and formate.

The mixtures are coarsely powdered, and the tube is tapped whilst filling so that no channel is left. The anterior layer may be rapidly heated. The only precautions required during the combustion are to avoid too tumultuous an evolution of gas, to cool well the vessel in which the ammonia is absorbed by acid, and to continue heating the tube until the last trace of water has distilled over, which requires about as long (25 minutes) as the combustion itself. For the titration, fluorescein or lacmoid is used, in order that the hydrogen sulphide present may have no influence. This method cannot be used for nitro-compounds, for nitrites, or for the nitrates of pyridine and chinoline. M. J. S.

Action of the Copper-Iron Couple on Nitrates and Nitrites in Sulphuric and Hydrochloric Acid Solutions. By K. Ulsch (*Zeit. anal. Chem.*, **31**, 392—404).—The author has now ascertained that his method for estimating nitric acid (Abstr., 1891, 960) can be simplified by working at ordinary temperatures. Iron alone reduces nitric acid in the cold very slowly and imperfectly, but when coated with copper, its reducing action is complete and rapid. Nitrites, and even a solution of nitric oxide in a ferrous salt, are similarly reduced to ammonia. 1 mol. of a nitrite ($M'NO_2$) causes a deficit of 8 atoms of hydrogen, and it is remarkable that whereas in estimating nitrates the presence of chlorides in any considerable quantity causes the reduction to be incomplete, with nitrites the results are perfectly correct even when hydrochloric acid alone is used. The injurious effect of the presence of chlorides on the nitric acid estimation can, however, be completely got rid of by adding some copper sulphate to the mixture of acid and nitrate which is to be introduced into the reaction flask, and warming to 60°. In this shape the method is suitable for the estimation of nitrates and nitrites in natural waters without the removal of chlorides.

The whole operation is carried out as follows:—The liquid containing the nitrates and nitrites is mixed with 10 c.c. of normal sulphuric acid and 10 c.c. of a 10 per cent. solution of crystallised copper sulphate, and is made up to 100 c.c.; 20 c.c. of this serves for each determination. The reaction flask is charged with 3 grams of iron powder, and the air is expelled by adding 10 c.c. of a 3 per cent. sulphuric acid. The flask is then connected with the azotometer, 2 c.c. more of the acid is run in, and then rinsed in by two additions (5 c.c. each) of the mixture to be assayed. The flask is plunged for two minutes into a water-bath at 60°, and is then shaken vigorously for two minutes. The solution is then drawn off and the flask cooled, and all is ready for the estimation. 20 c.c. of the above mixture is run in. Nitrites reveal their presence by producing the black solution of nitric oxide. The flask is shaken in the cold until this black colour just disappears. It is then warmed to 60° and shaken again. The deficit in the volume of hydrogen evolved is the sum of the deficits due to the nitrate and nitrite present. If it be wished to know the amount of each separately, the nitrite must be estimated by other means. M. J. S.

Estimation of Phosphoric Acid by the Molybdate Process. By O. Foerster (*Chem. Zeit.*, **16**, 109).—The precipitated phosphomolybdate is seldom quite soluble in ammonia, but a turbid liquid is obtained which refuses to give a clear filtrate. On adding magnesium mixture, the triple phosphate separates as a bulky precipitate, and the filtrate will be quite clear.

The magnesium precipitate is, as is well known, very difficult to wash free from adhering molybdate, which afterwards slightly increases the weight of the magnesium pyrophosphate. The precipitate will, however, be perfectly pure if the solution is gently heated before adding the magnesium mixture, but it must, of course, be allowed to cool, and be well stirred before filtering; the filtrate will be slightly turbid. The author washes with a solution containing 2·5 per cent. of ammonia and 5 per cent. of ammonium nitrate. As the molybdate chiefly sticks to the edges of the filter, these must be well washed.

L. de K.

Volumetric Estimation of Arsenic Acid. By G. Franceschi (*L'Orosi*, **15**, 192—194).—This method consists in the precipitation of the arsenate by ferric chloride, excess of ferric salt being indicated by potassium thiocyanate. The solution of the arsenate should be neutral and moderately concentrated (sodium acetate must not be used for neutralising), a small quantity of a dilute solution of potassium thiocyanate is added, and a decinormal solution of ferric chloride run in, until the blood-red coloration persists, after repeated agitation. Insoluble arsenates are first decomposed with sodium carbonate, and the product exhausted with water, neutralised with hydrogen chloride, and titrated. In presence of phosphates, satisfactory results may be obtained by first reducing the arsenate to arsenite, precipitating with hydrogen sulphide, oxidising the sulphide with nitric acid, and titrating.

Ferric salts may conversely be titrated with an arsenate, the end of the reaction being marked by the decolorisation of the thiocyanate; in the presence of salts of the alkaline earths, a solution of monopotassium arsenate should be employed. S. B. A. A.

Separation of Thioarsenic and Thioxyarsenic Acids. By L. W. McCay (*Zeit. anal. Chem.*, **31**, 372—375).—The addition of an acid to thioarsenates causes the precipitation of arsenic pentasulphide; but highly dilute, ice-cold solutions of the thioxyarsenates (M'_3AsO_3S) remain clear for some hours when feebly acidified with hydrochloric or sulphuric acid. The mixture of alkali salts is, therefore, dissolved in about 4000 parts of ice-cold water, and a small excess of sulphuric acid is added. The flask is plunged into a freezing mixture, and a tumultuous current of air is driven through the liquid for 15 minutes to expel the hydrogen sulphide liberated by the action of the acid on the thioarsenate. The precipitate is allowed to subside, rapidly filtered off by suction, in a Gooch crucible, and washed with water, followed by alcohol. After drying at 105—110°, it is washed six or eight times with carbon bisulphide, then with absolute alcohol, and is finally dried and weighed. The cold, clear filtrate is treated with chlorine, then concentrated, and transferred to a strong bottle of

200 c.c. capacity. A vigorous stream of hydrogen sulphide is passed through until the liquid becomes opalescent; the bottle is then stoppered, and heated for an hour in boiling water. The precipitated pentasulphide is collected and washed, first with water, and then thoroughly with absolute alcohol, to remove traces of sulphur, dried at 105—110°, and weighed. The process was tested with mixtures of Bouquet and Cloëz's potassium thioxyarsenate, H_2KAsO_3S, and a sodium thioarsenate of the composition $2Na_3AsS_4,15H_2O$, and the results agreed closely with the theory. M. J. S.

Toxic Action and Detection of Carbon Bisulphide. By A. Westberg (*Zeit. anal. Chem.*, **31**, 484—486).—The action of carbon bisulphide on the blood consists in the formation of methæmoglobin, with disintegration of the corpuscles. The action of xanthic acid is due solely to the carbon bisulphide liberated by its decomposition in the body.

In cases of poisoning by carbon bisulphide, that substance can be detected in the blood. About 12—15 c.c. of the blood is drawn directly from a vein into a flask, where it is mixed with half its volume of water, and distilled under reduced pressure in a stream of carbonic anhydride or hydrogen. The carbon bisulphide can be recognised in the distillate by treatment with an ethereal solution of triethylphosphine. This reagent will detect as little as 0·54 milligram of the bisulphide. By converting the bisulphide into potassium xanthate, evaporating to dryness in a vacuum, and testing the residue with sulphuric acid and ammonium molybdate, a red colour is produced, with as little as 0·667 milligram. The thiocyanate reaction seems to reach its lower limit at 1·05 milligrams. M. J. S.

Estimation of Calcium and Magnesium in Guncotton. By H. Schjerning (*Zeit. anal. Chem.*, **31**, 283—285).—The estimation of the ash and alkalinity of limed guncotton has usually been made by Abel's processes. In 1887, the practice was commenced of adding magnesia, with or without lime, in order to obtain greater alkalinity without increase of total ash. The author has employed the following process for the estimation of these alkaline earths:—About 5 grams of the guncotton weighed in a roomy platinum crucible is moistened with a mixture of equal volumes of alcohol and ether, which, after having been saturated with paraffin and filtered, has been mixed with one-fourth of its volume of water. Some fragments of solid paraffin are added, and the ether is set on fire. The obliquely placed crucible is rotated so that the guncotton may absorb the paraffin uniformly. The partially charred residue is then rubbed down with a rounded glass rod, and the crucible is covered and heated for 15—30 minutes over the blowpipe, occasionally removing the lid. The ash is weighed, then washed out into a porcelain basin, and heated to 90° with a measured excess of N/10 hydrochloric acid. The lime and magnesia dissolve along with traces of ferric oxide and alumina sufficiently large to interfere with the direct titration of the excess of acid. A little ammonium chloride and a drop of litmus tincture are added, and the mixture is made alkaline with N/10 soda.

The resulting precipitate, with the undissolved residue, consisting of ferric oxide, alumina, and silica, is filtered off, ignited, and weighed as "impurities." The alkali in the filtrate and washings is titrated with litmus and N/10 acid. The results are obtained by the formulæ:—

$$[0{\cdot}0028\,A - (B - C)] \times 2{\cdot}5 = \text{percentage of magnesia},$$
$$[(B - C) - 0{\cdot}002\,A] \times 3{\cdot}5 = \text{percentage of lime},$$

where A is the number of c.c. of N/10 acid consumed by 100 grams of the guncotton, B is the percentage of total ash, C the percentage of "impurities."

The following results are communicated: they seem to relate to a single specimen, although such is not clearly stated:—

	Ash.	MgO.	CaO.	Impurities.
By gravimetric methods..	2·30	1·10	0·79	0·39
By titration as above, average of 5 analyses.....	2·33	1·14	0·81	0·38

M. J. S.

Volumetric Estimation of the Metals of the Alkaline Earths and of some Heavy Metals. By D. Vitali (*L'Orosi*, **15**, 81—85).—This method depends on the complete precipitation of salts of barium, strontium, calcium, &c., by an alkaline carbonate, phenolphthaleïn being used to indicate the close of the reaction.

The neutral solution of the metallic salt is mixed with a few drops of an alcoholic solution of phenolphthaleïn, boiled to expel dissolved gases, and decinormal sodium carbonate run in until the coloration persists, even after boiling for a few seconds. Alkaline carbonates may conversely be titrated with a standard solution of barium chloride, and bicarbonates may be treated in the same way, after boiling their solutions until they are completely converted into the normal salts. Salts of silver, cadmium, manganese, lead, zinc, and magnesium may also be estimated by titration with sodium carbonate, if the precaution is taken to boil the solution well, in order to expel the carbonic anhydride liberated during the titration, and to add sodium carbonate until the coloration is persistent, even after boiling for some time. S. B. A. A.

A New Principle of Electrolytic Separation of Metals. By H. Freudenberg (*Ber.*, **25**, 2492—2493).—Le Blanc has shown (Abstr., 1891, 1405) that in a solution the amount of the electric charge is identical for one and the same ion, and that, therefore, the point of decomposition of an electrolyte may be exactly determined. As this value differs very considerably for the various metals, the author thought it probable that their separation may be brought about by employing currents of different E.M.F., and the experiments already made show that such is really the case. Thus, with a single Leclanché cell, having an E.M.F. of 1·35 volts, silver may be separated from copper and bismuth, and mercury from copper, bismuth, and arsenic. The analyses given show a very close agreement with the theoretical numbers. H. G. C.

Analysis of Galena and Lead Sulphate. By R. Benedikt (*Chem. Zeit.*, **16**, 43—44).—The author has found that both lead sulphide and lead sulphate are rapidly acted on by hydriodic acid, with formation of lead iodide; and also that this compound is readily converted into lead nitrate by the action of nitric acid.

To make an assay of galena, a known weight of the powdered ore is put into a deep porcelain capsule, moistened with water, and treated with a few c.c. of hydriodic acid of sp. gr. 1·7. The dish is covered with a watch-glass, and warmed on the water-bath. After a few minutes, the mixture is evaporated to dryness, and then heated with dilute nitric acid, when the lead iodide is converted into nitrate with separation of free iodine. The free nitric acid and the iodine are removed by evaporation, and the lead is finally converted into sulphate by the usual method.

The process also answers for the analysis of impure lead sulphate, but to prevent separation of sulphur the compound is mixed with a little amorphous phosphorus suspended in water, before being treated with the hydriodic acid. The test analyses are very satisfactory. The author thinks that the process will serve to estimate silver in presence of lead, as silver iodide is not decomposed by nitric acid.

L. de K.

Quantitative Separation of Silver and Lead. By R. Benedikt and L. Gans (*Chem. Zeit.*, **16**, 181—182).—Benedikt (see preceding abstract) has suggested that advantage may be taken of the different behaviour of the iodides of silver and lead towards nitric acid for a quantitative separation of these two metals. The authors now state that such is really the case, and after many experiments recommend the following process:—The solution, which should contain about 0·5 gram of metal, is diluted to 200 c.c., and then mixed with a solution of 1 gram of potassium iodide in 10 c.c. of water. After adding 10 c.c. of pure nitric acid, previously diluted with 10 c.c. of water, the mixture is heated on the water-bath until the yellow colour of the precipitate has changed to an orange-red. The lead iodide soon dissolves, and iodine is set free, which is expelled by adding boiling water and evaporating for some time on the water-bath, water being added from time to time. The precipitate is then pure silver iodide, and, according to the authors, is best collected on a weighed glass-wool filter, and dried at 110°.

The presence of copper, cadmium, and bismuth does not interfere, but if mercury is present the silver iodide retains mercuric iodide.

If the silver is present only in small quantities, for instance, in the case of argentiferous galena and pig-lead, as much as 10 or 50 grams of the sample must be operated on. The authors dissolve the metal in a mixture of nitric and tartaric acids, dilute to 300—500 c.c., add 10 c.c. of a 10 per cent. solution of potassium iodide, which is sure to be sufficient to precipitate all the silver, and then proceed as described. The test analyses are extremely satisfactory.

L. de K.

Estimation of Lead. By L. Medicus (*Ber.*, **95**, 2490—2492).—Lead may be estimated in an alkaline solution free from chlorides by precipitation as oxalate, which, after washing, is dissolved in nitric

acid and converted into lead peroxide by electrolysis. In presence of chlorides, however, the precipitation of the oxalate is incomplete, and the method is, therefore, not available for determining the amount of lead in galena after dissolving the mineral in hydrochloric acid; in this case, the lead chloride is dissolved in potash, carbonic anhydride passed through the solution for two hours, and the precipitated carbonate dissolved in nitric acid, and electrolysed. Another method is to dissolve the chloride in potash, and to pass a slow current of bromine vapour over the surface of the liquid until the lead peroxide sinks to the bottom and the supernatant liquid begins to assume a yellow colour; the lead peroxide is then filtered through asbestos in a perforated crucible. The analytical data given in the paper show that the method is capable of giving trustworthy results.

H. G. C.

Detection of Alum in Wines. By N. De Colli (*L'Orosi*, **15**, 118—120).—The following methods are stated to give satisfactory and concordant results:—

a. 100 c.c. of wine are evaporated to dryness in a porcelain dish on a sand-bath, and carefully heated until no more products of decomposition are evolved. The carbonised residue is pulverised in the dish, covered with dilute acetic acid, allowed to remain for 24 hours, boiled, filtered, evaporated to dryness, and heated until there is no further odour of acetic acid; water is then added, the mass again boiled, filtered, and ammonium chloride and ammonia added. Any alumina artificially introduced into the wine (as sulphate) is now precipitated; the aluminium tartrate naturally occurring in wine having been rendered insoluble by the incineration.

b. A definite quantity of the wine is evaporated to dryness in a platinum basin, and completely calcined, the process being hastened by the addition of ammonium nitrate. The ash is taken up with hot hydrochloric acid, filtered, the residue washed free from acid and sulphates, and the sulphates in the solution estimated. By comparison with the sulphates in the original wine, the amount of alumnium sulphate added (and decomposed by ignition) is ascertained.

S. B. A. A.

Estimation of Aluminium Phosphate. By C. Glaser (*Zeit. anal. Chem.*, **31**, 383—388).—The precipitation by ammonia of a solution containing alumina and excess of phosphoric acid gives, not the normal salt $AlPO_4$, but a basic aluminium phosphate. The same is the case when the precipitation is made with sodium acetate at 100°; but by heating to 70° only, and avoiding a higher temperature during the washing, the composition of the precipitate will agree exactly with the formula $AlPO_4$. The following modification of the usual process is therefore recommended. To the phosphate solution, which must not contain free chlorine, a drop of methyl-orange solution is added, and then ammonia, until the acid is all but neutralised. A few c.c of ammonium acetate now change the colour to yellow. The mixture is then heated to 70°, when the iron and aluminium phosphates are completely precipitated. If calcium phosphate is present, a little of it adheres to the precipitate, which should therefore be redissolved in hydrochloric acid and precipitated as before, after

adding a little sodium phosphate. Should the original liquid contain free chlorine, ammonia and then hydrochloric acid must be added before the indicator. The precipitate is washed on the suction filter with water heated to 70°, gently ignited, and weighed. To estimate the iron in it, it is covered with pure sodium carbonate and fused for 10 minutes, using the blowpipe. The fused mass is boiled with water and filtered hot, and the ferric oxide washed well with boiling water. Hot filtration is necessary to prevent the separation of an aluminium phosphate of the composition $Al_3P_2O_7$, which is very sparingly soluble in cold soda solution. The iron oxide is dissolved and reprecipitated by ammonia before weighing. M. J. S.

Estimation of Manganese in the various kinds of Iron. By H. Rubricius (*Chem. Zeit.*, **16**, 217—218; 459).—The author now proceeds as follows (compare this vol., p. 1030):—2 grams of the sample is dissolved in the smallest possible quantity of hydrochloric acid, and, after being somewhat diluted, oxidised with nitric acid. The whole is washed into a large glass vessel and diluted to about 500 c.c. No notice need be taken of any suspended carbon. Sodium carbonate is now added until a faint, permanent precipitate is produced, but this is at once cleared by the cautious addition of a few drops of nitric acid, and the ferric hydroxide precipitated with elutriated zinc oxide, but a large excess of it should be avoided. The precipitate, which is at first somewhat gelatinous, soon becomes more granular, and readily subsides. About 2 grams of magnesium sulphate is added, the liquid is gently heated, and then at once titrated with permanganate. The author uses this solution of such a strength that 1 c.c. equals 0·000637 gram of manganese.

The test analyses are very satisfactory. The process may also be applied to the estimation of manganese in ferruginous slags and ores. L. de K.

Stability of Potassium Permanganate Solution. By B. Grützner (*Arch. Pharm.*, **230**, 321—324).—The solutions were kept in glass-stoppered bottles, tied over with parchment paper, and in flasks fitted as wash-bottles, so that the solution might be withdrawn without removing the cork. Some of these vessels were exposed to diffused daylight, whilst others were kept in the dark. After one year, a 0·1 per cent. solution was unaltered in its relation to freshly prepared N/10 oxalic acid solution in every case. After $1\frac{1}{2}$ years, the same solutions had lost 2·61 per cent. of their contents of potassium permanganate when kept in daylight, and 0·94 per cent. when kept in the dark. A 0·3 per cent. solution was unaltered in every case after $1\frac{1}{2}$ years. The author succeeded in keeping N/10 sodium thiosulphate solution for six months unchanged; for this purpose, light should be excluded.

The method suggested by Vulpius and Holdermann for determining the metallic iron in *ferrum reductum* by the action of dilute sulphuric acid in the cold is not practicable, for much oxide of iron is dissolved at the same time. The method of shaking the sample with mercuric chloride solution and titrating with potassium permanganate is preferable if sufficient mercuric chloride be employed. A. G. B.

Hamburger's Method of Estimating Small Quantities of Iron. By HUPPERT (*Zeit. physiol. Chem.*, **17**, 87—90).—This method (*ibid.*, **2**, 195; **4**, 249), which consists in the reduction of iron oxide with sulphurous acid instead of zinc, has been criticised by some, but the author finds that it is simple, and gives absolutely correct results.

W. D. H.

Detection of Nickel and Cobalt. By F. J. HAMBLY (*Chem. News*, **65**, 299).—The mixed sulphides of nickel and cobalt, obtained in the ordinary course of analysis, are dissolved in hydrochloric acid and potassium chlorate, and evaporated to dryness and redissolved; or the chlorine is boiled off and the excess of acid neutralised. The solution is treated with an excess of potassium cyanide beyond that required to dissolve the precipitate at first formed (boiling is unnecessary), then rendered alkaline with sodium hydroxide, and twice the volume of bromine-water added; on gently heating, the whole of the nickel is precipitated as nickelic hydroxide, whilst the cobalt remains in solution as potassium cobalticyanide. Both metals may be identified in the ordinary manner.

D. A. L.

Analysis of Chromite. By E. WALLER and H. T. VULTÉ (*Chem. News*, **66**, 17—18).—$\frac{1}{2}$ to 1 gram of the pulverised chromite is dropped on to and fused to complete decomposition with five or six times its weight of a molten flux, consisting of 2 parts of borax glass and 3 parts of fusion mixture, previously fused together, and coarsely pulverised. The fused mass is treated with water, the solution evaporated with ammonium nitrate until ammonia ceases to be evolved, and then taken to dryness with a few drops of nitric acid; the residue is redissolved in water containing a small quantity of nitric acid, and the solution, containing only chromates and nitrates, is treated with hydrochloric acid and sulphurous acid, of which the excess is boiled off. The solution is now neutralised with ammonia, boiled in presence of some ammonium sulphide, the precipitate redissolved in hydrochloric acid, reprecipitated as before, ignited, and weighed as chromic oxide.

D. A. L.

Estimation of Small Percentages of Gold and Silver in Base Metals, Mattes, &c. By C. WHITEHEAD (*Chem. News*, **66**, 19—20).—The following method is devised for estimating gold and silver in base ores, crude copper, zinc, mattes, &c. The material, the quantity depending on the proportion of precious metal present, is dissolved in nitric acid, diluted with water, mixed with 50 grams of lead acetate, 1 c.c. of dilute sulphuric acid added, and filtered; the precipitate, which contains any gold that may be present, is examined in the usual way. The filtrate is made up to a litre and in 500 c.c. lots, precipitated completely with a saturated solution of sodium bromide; the precipitates, after washing and drying, are run down with sodium carbonate, flour, and borax, the buttons cupelled, and the silver beads weighed separately.

D. A. L.

Volumetric Estimation of Gold. By G. Franceschi (*L'Orosi*, **15**, 112—115).—This method consists in the precipitation of gold from its solutions by stannous chloride or an alkaline stannite, excess of the reagent being indicated by the blue coloration which it produces in contact with phosphomolybdic acid.

The stannite must be freshly prepared. A decinormal solution is readily obtained by dissolving tin (7 grams) in concentrated hydrochloric acid in an atmosphere of carbonic anhydride, adding a saturated solution of Rochelle salt and a slight excess of pure sodium hydrogen carbonate, standardising with decinormal iodine solution, and diluting to the extent required. During the titration of the gold solution, a small drop is taken out at intervals, dropped on a piece of filter paper, and the periphery of the spot touched with a rod dipped into a solution of phosphomolybdic acid; a bluish coloration is produced at the point of contact if there is the slightest excess of stannite. A mixture of solutions of ferric sulphate and ferricyanide of potassium may also be used as an indicator, but the reaction is not so delicate. S. B. A. A.

Testing the Purity of Platinic Chloride. By A. F. Holleman (*Chem. Zeit.*, **16**, 35).—Platinic chloride is supposed to be fit for use as a reagent if it dissolves completely in absolute alcohol, and after ignition yields nothing to dilute nitric acid. The author, getting unsatisfactory results when engaged in potash estimations, suspected his platinic chloride, and found it to contain an appreciable amount of sulphuric acid.

As his potash solution contained traces of baryta, the potassium platinochloride got, in consequence, contaminated with more or less barium sulphate. L. de K.

Extraction of the Dissolved Gases from Water. By F. Hoppe-Seyler (*Zeit. anal. Chem.*, **31**, 367—372).—The extraction is effected by boiling the water in a vacuum, and transferring the gases to a measuring tube by a mercury pump. The apparatus consists of six glass pieces united by rubber tubes of 5 mm. bore and 5—7 mm. thickness. The first vessel, C, is a mercury reservoir; then follow in series three tubes of pipette form, C′, A, and B, of which A, of 250 to 500 c.c. capacity, is the collection vessel for the water. C′ and B are much narrower than A. All the rubber tubes connecting these vessels are closed by compression clips. The tube B is connected to the side branch of a tube D, of the form of a gas burette, of which both the side and upper limbs are furnished with good glass stopcocks. The lower end of D is joined by a rubber tube, 1 metre in length, to a tubular mercury reservoir E, whilst the upper limb is provided with a gas delivery tube leading to a mercury trough. To collect the water, A is placed in a vertical position and filled with mercury by influx from C. The upper end of A is then connected by tubing with the water supply, and the mercury is allowed to flow back into C. The water is thus transferred without contact with air. A is now placed in an oblique position; B is attached, and by alternately lowering and raising the reservoir E, with suitable manipulation of

the stopcocks, the tube B is exhausted of air and filled with mercury. The compression clips are now all opened, and the water in A is vigorously boiled, the reservoir C being at such a level that the pressure in A is 5—10 cm. below that of the atmosphere. After five minutes' boiling, the lower clip is closed, and the gas in B is pumped over into D and expelled into a tube standing in the mercury trough. The clip is again opened and the boiling repeated as long as any traces of gas are obtained. In the absence of carbonic acid, 6 to 10 repetitions are sufficient, but it seems to be impossible to expel carbonic anhydride from water completely, even with 40 boilings. The whole operation requires $\frac{3}{4}$—$1\frac{1}{2}$ hours. M. J. S.

A New Colour Standard for Natural Waters. By A. HAZEN (*Amer. Chem. J.*, **14**, 300—310).—It is found that the Nesslerised ammonia standard of colour, although the best hitherto used, is objectionable on account of the change in the standard colours with slight variations in manipulation, the colours of the lower standards depending quite as much on the quantity and quality of the Nessler reagent used as on the ammonia. Further objections exist in the facts that the numbers expressing the colours are not directly proportional to the colours themselves, and that waters having colours less than that of Nesslerised distilled water find no place in its scale.

Standard colours prepared from a mixture of solutions of platinum and cobalt chlorides are recommended, as the colour of such solutions is, within wide limits, independent of acidity and temperature, and the standards are quite stable even in direct sunlight when containing a moderate amount of hydrochloric acid.

The colour of the standards can be made to match that of natural waters, allowing more accurate comparisons than are possible with Nesslerised ammonia. The figures obtained are directly proportional to the actual colours. W. T.

Volumetric Analyses by means of Potassium Ferrocyanide or Ferricyanide. By C. LUCKOW (*Chem. Zeit.*, **16**, 164—165; 835—838).—The author (compare this vol., p. 1129) recommends that the formula of potassium ferrocyanide should be doubled. The standard solution should therefore be made by dissolving 42·2 grams of the salt in 1 litre of water (a N/20 solution). The ferricyanide solution is made by taking 32·9 grams of potassium ferricyanide in 1 litre of water. The solutions may, if desired, be diluted to any given strength, so that, for instance, 1 c.c. will show exactly 0·005 of metal. Both solutions are best preserved in brown glass bottles, and, according to Moldenhauer, the ferrocyanide should be made alkaline to preserve it better. The general properties of the ferrocyanides and ferricyanides of the heavier metals are as follows:—They are coloured compounds, which are mostly insoluble in water, and readily deposit from saline solutions, but remain more or less suspended in pure water. Acids, particularly hydrochloric acid, slightly increase the solubility. At first no difficulty is experienced in filtering, but as soon as the attempt is being made to wash with pure water, some of them

have a tendency to pass through the filter. After prolonged drying at 60—70°, the granular precipitates form brittle masses readily crushed; the more bulky precipitates look more like dried gluten. Some precipitates may be dried at 200° without undergoing any marked decomposition; others, for instance, those precipitated from an ammoniacal solution, sensibly diminish in weight. Some ferricyanides are decomposed at 100°, whilst the manganese compound actually begins to glow at that temperature. On ignition, and repeated treatment with nitric acid, the metallic oxides are left. The action of ammonia is peculiar; some compounds dissolve without decomposition, but tin compounds gradually deposit the tin as hydroxide. Other metals, such as zinc, although their hydroxides are soluble in ammonia, are precipitated from their ammoniacal solution. The author also calls attention to the various, in some cases impossible, quantities of combined water which these compounds are supposed to contain, and recommends further investigation in this direction.

The reaction between potassium ferrocyanide and metallic solutions is not, however, always complete, and then in most cases the precipitates contain more or less undecomposed potassium or ammonium ferrocyanide. When working with ferricyanide, the reaction is generally more complete. The solutions should, therefore, always be checked with a known quantity of metallic salt; the titrations being effected under like conditions of reactions, &c. To show the necessity of this, the following results obtained by the author may be quoted:—

1. Action of potassium ferrocyanide on zinc: 1 c.c. of a N/20 solution = 0·00975 gram of zinc in acid solution, 0·0081 gram in neutral solution, and 0·13 gram in ammoniacal solution.

2. Action of potassium ferricyanide on cobalt: 1 c.c. of N/20 solution = 0·0088 gram of cobalt in neutral or acid solution, and 0·0103 gram in its ammonium carbonate solution.

Similar results were obtained with several other metals.

L. de K.

Estimation of Iodoform. By H. D. Richmond (*Analyst*, **17**, 7).—When iodoform is heated with alcoholic soda, a somewhat complex reaction takes place, but its 70 per cent. of iodine is practically converted into sodium iodide. On this fact, the author has based the following method for the testing of commercial iodoform.

About 0·15 gram of the sample is dissolved in alcohol, an excess of alcoholic soda is added, and, after about 10 minutes' digestion near the boiling point of the alcohol, the excess of spirit is evaporated. The residue is taken up with water, slightly acidified with dilute nitric acid, and again neutralised by a small quantity of calcium carbonate. The solution is then titrated with a weak standard solution of silver nitrate with potassium chromate as indicator. The method does not take more than half an hour to perform. Should the iodoform be obtained in ethereal solution, as, for example, in the estimation of acetone, the ether need not be evaporated, but can be mixed directly with the alcoholic soda. The test analyses are very satisfactory.

L. de K.

The Oxidation of Alcohol by Permanganate. By R. Benedikt and J. Neudörfer (*Chem. Zeit.*, **16**, 77—78).—Benedikt and Zsigmondy were the first to observe that ethyl alcohol, under certain conditions, is oxidised to oxalic acid by the action of alkaline permanganate.

The authors have been for some time engaged in trying to find out under what conditions the oxidation will be quantitative, so as to get a really simple and direct method for the estimation of alcohol, as this is still a desideratum. Their efforts have not as yet been attended with much success, as the largest amount of alcohol found did not exceed 64 per cent. of the whole; but as other chemists may, perhaps, be more successful, they thought it as well to call attention to the matter.

The experiments were made in much the same way as glycerol estimations are performed according to Benedikt and Zsigmondy's method, the best results being obtained when the 2 per cent. solution of the alcohol was added to the boiling alkaline permanganate.

L. de K.

Estimation of Glycerol in Wine. By G. Baumert (*Arch. Pharm.*, **230**, 324—331; compare Abstr., 1890, 426, 427).—The distillation vessel has the form of a U-tube, the wider limb of which is expanded to a pear-shaped bulb, and is connected with a Liebig's condenser. The narrower limb is surrounded by an air-bath, and is connected with an iron spiral tube, which is heated by burners and is for the admission of superheated steam. The wine (50—100 c.c.) is evaporated in a dish with precipitated calcium carbonate (1—2 grams) to about one-half, and introduced into the wide limb of the distillation flask, which is then heated until no more water condenses in the upper part. Superheated steam is now admitted, and the distillate collected in a 200 c.c. flask, to which volume it is subsequently diluted. Potassium hydroxide (10—12 grams), free from oxalate, is dissolved in the dilute distillate, and, after cooling, a cold saturated solution of potassium permanganate is added in excess. The mixture is boiled for some time and, after half an hour, a stream of sulphurous anhydride (from hydrogen sodium sulphite and sulphuric acid) is passed through it until the liquid is colourless, and all separated manganese oxides have dissolved. Acetic acid is next added, all sulphurous anhydride expelled by boiling, and the oxalic acid precipitated by calcium chloride solution. The precipitate will contain calcium sulphate, and cannot be weighed directly; it is washed with hot water, decomposed by sulphuric acid, and titrated with potassium permanganate solution. 90 parts of oxalic acid are equivalent to 92 parts of glycerol.

Planchon's method, whereby the distillate is oxidised completely by acid potassium permanganate solution, and the resulting carbonic anhydride weighed, does not yield such good results as the method described.

A. G. B.

New Test for Sugar in Urine. By G. Hoppe-Seyler (*Zeit. physiol. Chem.*, **17**, 83—86).—Baeyer (*Ber.*, **13**, 2260) has shown that indigo an be formed artificially from orthonitrophenylpropiolic acid by boiling it with alkalis, and reducing substances like dextrose.

This may be applied to the detection of sugar in urine. A $\frac{1}{2}$ per cent. solution of the acid in sodium hydroxide is the reagent used, and it keeps unchanged for months. Diabetic urine diluted 10 times gives a deep blue on boiling a small quantity with about five times its bulk of the reagent. The advantages claimed for the test are (1) a convenient reagent, (2) small quantities of urine will suffice, (3) albumin does not interfere with the reaction. W. D. H.

Improvement in the Method of Estimating Aldehydic and Ketonic Oxygen. By H. Strache (*Monatsh.*, **13**, 299—315; compare Fischer, *Ber.*, **17**, 572).—The author has previously (this vol., p. 546) described a method for the estimation of aldehydic and ketonic oxygen, in which the substance under investigation is added to an excess of phenylhydrazine, whereby a hydrazone is formed, and the excess of phenylhydrazine is afterwards determined by measuring the nitrogen evolved on treating it with hot Fehling's solution. The method is, however, liable to two sources of error; one, due to the fact that, under some conditions, Fehling's solution and phenylhydrazine may react with formation of aniline, lowering the results; the other raising them, owing to the tension caused by the presence of a variable quantity of benzene vapour in the gas. To eliminate these errors, the author has rearranged the apparatus employed in such a way that the solution of the compound under investigation is allowed to fall into the hot Fehling's solution; and he passes several drops of benzene into the measuring tube containing the nitrogen, the volume of the gas being afterwards corrected for the tension of the vapours of both water and benzene. Under such improved conditions, constant but, owing to the imperfect displacement of air, somewhat too high results are obtained. The further necessary correction was determined by conducting experiments in blank, and, after making due allowance, the results were satisfactory. Acetone and many other compounds gave numbers which accurately agreed with the calculated values, but anomalous results were obtained with benzile and benzophenone. Both of these, when alcohol was employed as a solvent, gave numbers corresponding with only half the oxygen present in the carbonyl groups of the compounds.

G. T. M.

Estimation of Thiocyanacetone. By J. Tcherniac (*Ber.*, **25**, 2621—2626).—See this vol., p. 1426.

Estimation of Hydrocyanic Acid. By G. Venturoli (*L'Orosi*, **15**, 85—88).—It is often impossible to estimate hydrogen cyanide in mixtures without previously isolating it by distillation; the following process is proposed for use in such cases:—

The solution containing the hydrogen cyanide is introduced into a flask of about 300 to 400 c.c. capacity, and a current of pure hydrogen passed into the liquid, the escaping gas being led into a decinormal solution of silver nitrate. In about an hour the whole of the hydrgen cyanide will have been carried over, and the silver remaining in solution is then titrated with potassium ferrocyanide. In the presence of metallic cyanides, dilute sulphuric or tartaric acid is introduced into

the flask before commencing the process. Cyanide of mercury must be decomposed with hydrogen sulphide, the solution acidified with tartaric acid, neutralised with freshly precipitated calcium carbonate in order to fix any ferro- or ferri-cyanides present, hydrogen is then passed in, and the issuing gases led first through a solution of bismuth nitrate to remove hydrogen sulphide, and then into the silver solution.

Separation of Malic Acid from Succinic, Citric, and Tartaric Acids. By C. Micko (*Zeit. anal. Chem.*, **31**, 465—468; from *Zeit. allgem. österr. Apotheker-Vereins*, **30**, 151).—The solution, which must contain the acids (about 0·7 gram) as potassium salts and be feebly acid, is evaporated in a flask to about 10—15 c.c., then mixed with 0·5 gram of barium acetate and excess of baryta water, and gradually heated to boiling. The bulky precipitate is collected and washed with baryta water, but not too long, as the precipitate would begin to redissolve. The filtrate is heated nearly to boiling and treated with carbonic anhydride until nearly or quite neutral. Excess of baryta water is again added, and after 24 hours the precipitate is collected and washed as before. The excess of baryta is now removed by passing carbonic anhydride through the hot liquid, filtering, and washing with hot water. The filtrate and washings are feebly acidified with acetic acid, concentrated to 10—25 c.c., once more boiled with baryta, then treated with carbonic anhydride, and again made alkaline with baryta. On filtering after 24 hours, and washing the precipitate with baryta water, the filtrate will contain all the malic acid and be free from the other acids. The baryta is now thrown down hot with carbonic anhydride, and the acidified filtrate is concentrated and precipitated by a small excess of potassium carbonate. The filtrate is acidified, evaporated, mixed cold with an excess of acidified lead acetate (5 c.c. of 1 : 5), and then with 120 c.c. of 80 per cent. alcohol. After 48 hours, the precipitate is collected and washed, first with cold, then with hot 80 per cent. alcohol. Should the filtrate be turbid, it is boiled in a flask with reflux condenser until clear, and then set aside for 48 hours. The small precipitate is collected, and washed with cold alcohol. The lead in the two precipitates is determined, and the amount of malic acid calculated therefrom.

M. J. S.

Estimation of Tartar in Sweet Wines by the Method of Berthelot and Fleurieu. By E. Ackermann (*Zeit. anal. Chem.*, **31**, 405—407).—The author has met with a sweet Greek wine, which, like the Carlowitz examined by Petrowitsch (Abstr., 1886, 652), gave no crystalline precipitate when mixed with ether-alcohol. Petrowitsch inferred from this the absence of tartar, and assumed that the whole of it had been precipitated by the 14·65 vols. per cent. of alcohol, under the conditions of long keeping in a very cold cellar. In both cases, however, a soft, slimy, brown precipitate was obtained. In the author's case, this proved to be chiefly sugar, containing, however, tartar, the crystallisation of which was prevented by the syrup. After complete fermentation of the wine, a crystalline precipitate of tartar could be obtained, but none of the slimy matter. The limit of alcoholic strength at which a wine cannot retain tartar is, therefore,

above the 14·8 vo's. per cent. present in this specimen. Since a quantitative experiment with an artificial sweet wine showed that after complete fermentation the whole of the tartar added could be recovered, it is recommended that sweet wines should be fully fermented before precipitating with ether-alcohol.

To the assertion of Dietzsch that a wine from which no tartar can be precipitated in the course of 24 hours must be artificial, it may further be objected that genuine wines, which have been over-plastered, will have lost the whole of their tartaric acid as calcium tartrate. M. J. S.

Separation of Salicylic from Benzoic Acid. By Miss J. Schaap (*Chem. News*, **66**, 42—43).—By treating solutions containing salicylic and benzoic acids with excess of bromine, the former is wholly precipitated as the dibromo-derivative, whilst the benzoic acid remains in solution. D. A. L.

Estimation of Fat in Milk. By H. Leffmann and W. Beam (*Analyst*, **17**, 83—84).—The authors proceed as follows:—15 c.c. of milk is put into a 30 c.c. bottle, the neck of which is graduated so that a volume of 1·5 c.c. is divided into 86 parts. 3 c.c. of a mixture consisting of equal parts of fusel oil and hydrochloric acid is added, and strong sulphuric acid is poured in slowly, with agitation, until the bottle is filled nearly to the neck. The liquid becomes hot, and the caseïn dissolves to a dark, reddish-brown liquid. The neck is now filled to near the zero point with a hot mixture of sulphuric acid and water, and the bottle whirled for one to two minutes in their centrifugal machine, but in the case of skimmed milks from three to four minutes are required. The volume of the fat may then be read off, each division on the neck representing 0·1 per cent. of butter-fat.

The test analyses are satisfactory.

O. Hehner (*Analyst*, **17**, 102) also obtained satisfactory results by using one of the author's machines. If the specific gravity of the sample is carefully taken, the percentage of total solids contained in the milk may be found by calculation, using Hehner's formula, or by means of Richmond's slide rule, and a milk analysis may thus be finished in a very few minutes. L. de K.

Detection of Foreign Fats in Butter. By J. Erdélyi (*Zeit. anal. Chem.*, **31**, 407—410).—Pure butter fat dissolved in three times its volume of cumene (boiling point 165° at 758 mm. bar.) gives a solution which remains clear at 0° for at least an hour, and usually for much longer, whilst mixtures of butter with margarine and with lard become turbid much earlier. The mode of procedure was to filter the fat, cool it for 24—48 hours in a refrigerator, place 2 c.c. of it with 6 c.c. of cumene in a clear, dry test-tube of 2 cm. diameter, and after 24 hours at ordinary temperature to plunge the tube into powdered ice, and, after the lapse of an hour, examine it at short intervals. Further investigation of the method is solicited. M. J. S.

Horse Fat. By C. Amthor and J. Zink (*Zeit. anal. Chem.*, **31**, 381—383).—The following numbers are mean values from two determinations. The melting points were the temperatures at which the fats became transparent in capillary tubes:—

	Kidneys.	Neck.	Flank.	Foot.
Consistence.	Soft.	Like fresh butter.	Like butter.	Semi-fluid.
Colour.	Golden yellow.	Deep orange.	Golden yellow.	Pale. yellow.
Specific gravity at 15°	0·9320	0·9330	0·9319	0·9270
Melting point	39°	34—35°	36—37°	—
Solidifying point	22°	30°	20°	—
Melting point of the fatty acids	36—37°	41—42°	39—40·5°	—
Solidifying point of fatty acids	30—30·5°	32—33°	31—32·5°	—
Hehner's number	95·47	95·42	94·78	—
Reichert's number	0·33	0·22	0·38	—
Saponification number	198·7	199·5	197·8	—
Acidity (milligrams of potassium hydroxide for 1 gram of fat)	1·73	2·44	1 84	—
Acetyl number	6·64	13·74	11·62	—
Iodine number	81·09	74·84	81 60	90·30
Iodine number for the fatty acids	83·88	74·41	83·37	—

With lapse of time, horse fat becomes more fluid, and a crystalline deposit separates from it. It also becomes nearly colourless with age (Abstr., 1889, 1076). M. J. S.

New Method for the Estimation of Unsaponifiable Matter in Fats. By W. Mansbridge (*Chem. News*, **65**, 253—255).—The ether method proving unsatisfactory for the extraction of unsaponifiable matter from wool, grease and fat, the following method has been devised by the author. After the mass has been decomposed with acid, subsequent to saponification, a convenient quantity is treated with 50 c.c. of methylated spirit saturated with light petroleum (b. p. 43°), and 50 c.c. of the light petroleum is then added; the whole is heated to boiling in a reflux apparatus, and after it has been cooled slightly, it is neutralised with a measured quantity of semi-normal potassium hydroxide, and placed in a separating funnel; if the separation is imperfect, a few c.c. of boiling alcohol is added. The petroleum layer is then separated, and washed by agitating, first with 50 c.c. of water at 38°, or with 50 per cent. alcohol, and then with 40 c.c. of 70 per cent. alcohol. The distillation is conducted, by preference, over an argand flame turned down to a blue light, and the "drying" completed by blowing in the warm flask, while it is slowly rotated. A second extraction with the light petroleum is usually found to remove practically all the unsaponifiable matter from the alcoholic soap solution. D. A. L.

New Reaction of Xanthine and Allied Compounds. By E. DRECHSEL (*Ber.*, **25**, 2454).—Xanthine, hypoxanthine, and guanine, like alkaline urates, form compounds with cuprous oxide. If their ammoniacal solutions are mixed with Fehling's solution, boiled, and solution of dextrose dropped in, white, flocculent precipitates of the cuprous oxide compounds are formed. Similar precipitates are formed in a cold solution if a hydroxylamine salt is added.

C. F. B.

Detection of Atropine. By L. FABRIS (*Gazzetta*, **22**, i, 347—350).—A patient at a hospital in Padua, who had for some time been treated by daily injections of 6 milligrams of strychnine nitrate, died a few hours after receiving an accidental injection of 3 milligrams of normal atropine sulphate, exhibiting acute symptoms of atropine poisoning. At the *post-mortem*, the presence of bilateral mydriasis, and of congestion of the meninges and of the cerebellum became evident. On examining the viscera by the Stas-Otto method, clear indications of the presence of an alkaloïd were obtained, but on applying the special reactions for strychnine and atropine, the results were negative. To test the possibility of these alkaloïds obscuring each other's reactions, mixtures of 3 per cent. solutions (the strength of the injections) of strychnine nitrate, and atropine sulphate were tested with sulphuric acid and potassium dichromate, and by Vitali's reaction, with the following results. A mixture of equal parts of the solutions gave the strychnine reaction very clearly, but the atropine reaction not at all; a mixture of 1 of strychnine with 3 of atropine gave the strychnine reaction, but not that of atropine; a mixture of 1 part of strychnine with 4 of atropine gave indistinct reactions for both alkaloïds; a mixture of 1 of strychnine to 5 of atropine gave a momentary atropine reaction; the characteristic violet coloration is, however, immediately superseded by a reddish tint. Vitali's reaction was not clearly obtained until at least 9 parts of the atropine solution were added to 1 of strychnine. It further appeared that a solution of strychnine too dilute to give the characteristic reactions of that alkaloid may effectually obscure the atropine reaction; thus 1 drop of the 3 per cent. strychnine solution diluted with 10 drops of water scarcely yields the strychnine reaction; on adding 4 drops of atropine solution to this, no reaction for atropine could be obtained.

A piece of meat injected with 0·05 c.c. of a 3 per cent. solution of each of the alkaloïds, and extracted by the Stas-Otto process, yielded a barely sensible strychnine reaction and no trace of atropine. Finally, on injecting a mixture of 3 parts of the 3 per cent. strychnine solution and 1 part of the atropine solution into a frog, paralysis of the lower limbs and a great augmentation of the nervous sensibility ensued; on introducing the mixture into the eye of a dog, distinct mydriasis was observed in fifteen minutes. It thus appears that in cases of poisoning by atropine, the physiological evidence may be conclusive when the chemical tests yield doubtful results.

S. B. A. A.

Analysis of Coffee Substitutes. By MOSCHELES and R. STELZNER (*Chem. Zeit.*, **16**, 281—282).—Imitation coffee may, as a rule, be

distinguished from the real article by yielding a much higher aqueous extract. According to the author's experience, the best way of determining the amount of extract in a sample is as follows :—25 grams of the compound is rubbed in a mortar, introduced into a litre flask, and digested with about 500 c.c. of water on the water-bath for half-an-hour ; the mixture is now made up to the mark with water, and allowed to cool. Some of the liquid is filtered, and 50 c.c. of the filtrate evaporated in a platinum dish, containing a known weight of dry sand. Pure coffee, when treated in this manner, gives from 20 to 30 per cent. of extract only ; some coffee substitutes yield as much as 72 per cent. L. DE K.

Approximate Estimation of Adulteration of Earth-nut Cake and Meal. By L. HILTNER (*Landw. Versuchs-Stat.*, **40**, 351—355).—The substance (about 0·2 gram) is placed on an inverted plate and completely moistened with tincture of iodine. After a few minutes, the meal is distributed over the whole surface by means of a jet of water from a wash-bottle. The liquid must still contain iodine, and is made clear by the addition of a few drops of alcohol. The water is now drawn off, and the substance air dried and placed on green paper. By means of a lens of low power, the particles of cake which are blackened by the iodine are readily separated from the poppy seeds ; the separated portions are then weighed. In an experiment made with known quantities, 10·64 per cent. of poppy seed was found instead of 10 per cent. In this case, the particles of the ground cake were rather large, and the separation therefore easy. When there are finely-powdered, dust-like particles, the separation is more difficult. After treatment with iodine and drying, the substance is sifted in a 0·25-mm. sieve and the separation in the coarse portion is made as usual. In two check experiments, the results were within 5 per cent. of the actual amount. The percentage of poppy seed in the portion passing through the sieve may be determined by separating under a microscope, but the amount is generally small, and may be judged without actual separation.

The method is quickly carried out, and is applicable not only in the case of adulteration with poppy seed, but in nearly every case, as the substances used for adulteration are nearly all free from starch.

N. H. M.

Analysis of Peptones. By C. W. HEATON and S. A. VASEY (*Analyst*, **17**, 28—34).—After a careful trial of all the processes at present in use, the authors have found that by a combination of several of them the analysis may be simplified. No new reagents are suggested.

It is best to work with a tolerably concentrated solution. Any portion insoluble in warm, but not boiling, water must be filtered off, and treated separately for nitrogen. If a jelly is under examination, it must be liquefied by heat or dilution. In the following scheme, a strength of about 20 per cent. of solid matter is assumed, including mineral salts. It is best to make separate estimations of water, ash, and total nitrogen.

1. *Water ; Ash ; Total Nitrogen.*—Estimated as usual.

2. *Albumin ; Coagulable Gelatin ; Albumose ; Peptone.*—40 grams of fluid peptone is dropped gradually into 300 c.c. of absolute alcohol, contained in a large, weighed beaker, and the mixture agitated by gentle centrifugal motion. The above-named compounds soon separate, and can be washed with alcohol by decantation. The alcoholic liquid (*stock alcoholic solution*) is kept for further investigation. The precipitate in the beaker is dried to constant weight at 100°.

(*a.*) *Albumin.*—The precipitate is digested with warm water, and washed on a tared filter. The insoluble residue represents the albumin. The filtrate is diluted to 250 c.c., and constitutes the *stock aqueous solution.*

(*b.*) *Albumose and Gelatin.*—25 c.c. of the stock aqueous solution is evaporated to a few c.c., treated with a saturated solution of ammonium sulphate, raised to nearly 100°, and quickly cooled with centrifugal agitation. The precipitate is collected on a tared filter, washed with ammonium sulphate, dried, and weighed. The adhering ammonium sulphate is estimated by means of barium chloride, and allowed for.

(*c.*) *Albumose.*—50 c.c. of the stock aqueous solution is heated to near 100°, and then treated with 30 c.c. of Stutzer's reagent (an emulsion of cupric hydroxide in dilute glycerol). The precipitate is washed on a filter with hot water, and the nitrogen contained in it estimated by the Kjeldahl method.

(*d.*) *Gelatin.*—A direct estimation may be made as follows:—The filtrate from the copper precipitate is concentrated to a few c.c., in a beaker previously weighed with a glass rod in it; saturated solution of ammonium sulphate is then added, the mixture raised nearly to the boiling point, and then quickly cooled with centrifugal agitation. The gelatin now separates and adheres to the sides and bottom of the beaker, particularly if well manipulated with the rod. After a slight washing with iced water, it may be dried and weighed. As it contains some ammonium sulphate, this must be estimated and allowed for.

The Stock Alcoholic Solution.—This is made up to 500 c.c., and divided into fractions for separate treatment.

(*a.*) *Gelatin Soluble in Alcohol.*—100 c.c. is evaporated to dryness, taken up with warm water, and estimated, as directed, by means of ammonium sulphate.

(*b.*) *Urea, &c.*—50 c.c. is evaporated to dryness, and treated with sodium hypobromite, but the nitrogen cannot safely be calculated as urea.

(*c.*) *Nitrogen.*—100 c.c. is evaporated and treated by the Kjeldahl process. After allowing for the nitrogen present as gelatin, the difference multiplied by 3·12 gives the amount of crystallisable nitrogenous compounds calculated as creatine.

(*d.*) *Ash Soluble in Alcohol.*—Another fraction may be used for the estimation of the ash. L. DE K.

Zune, detection of resin oil in terebenthene, 923.

INDEX OF SUBJECTS.

ABSTRACTS. 1892.

And also to Transactions, 1892 (marked TRANS.); and to such papers as appeared in the Proceedings during the Session 1891—1892 (Nos. 101 to 114; Nov., 1891, to July, 1892), but not in Transactions (marked PROC.).

A.

Absinthin, from *Artemisia absinthum*, 1240.
Absorbent power of coloured salts and electrolytic dissociation, 757.
Absorption and digestion of fat oils by plants, 1118.
—— coefficients of gases, 1043.
—— of gases by liquids, 556.
—— spectra of thin metallic films, 1037.
—— without osmosis, 646.
Acenaphthalide, ortho- and para-nitro-*a*-, action of bromine on a mixture of, PROC., **1891**, 186.
Acenaphthene, oxidation of, 863.
Acenaphthenequinone, 864.
Acetal, amido-, preparation of, 1327.
Acetaldehyde, action of zinc and ethyl chloracetate on, 1300.
—— condensation of, with aniline, 1191.
Acetaldehydeaniline, 1191.
Acetaldoxime, 951.
—— action of hydrocyanic acid on, 1196.
—— preparation of, TRANS., 473.
Acetaldoximes, existence of two crystalline, TRANS., 470; PROC., **1892**, 135.
Acetalylcarbamide, 1327.
Acetalylmetaxylylthiocarbamide, 1329.
Acetalyl-*a*-naphthylthiocarbamide, 1331.
Acetalylparatolylthiocarbamide, 1328.
Acetamide, brom-, 827.
Acetamidine nitrite, 53.
—— picrate, 705.
Acetamidobenzylacetanilide, ortho-, 81.
Acetamidocarbazole, 616.
Acetamidonitrosocarbazole, 616.
Acetamidophenylsulphonepropionic acid and its halogen derivatives, 1090.
Acetamidotolyloxamethane, 599.
Acetamidotolylurethane, 1203.
Acetanhydrocitric acid, TRANS., 1003.
—— —— action of aniline on, TRANS., 1006.
—— —— conversion of, into aconitic acid, TRANS., 1007.
Acetanilide, nitrodibromo-, 1205.
Acetanilidobutyric acid, 1338.
Acetanilidoisobutyric acid, *β*-, 1339.
—— lactone, 1339.
Acetenyltrimethylammonium hydroxide, 905.
—— salts, 807.
Acetic acid, heats of combustion and formation of, 1139.
—— —— oximido-, 699.
—— —— production of, from cellulose, 1421.
—— fluoride, 1068, 1069.
—— sulphide, 300, 581.
Acetimido-*β*-chlorethyl ether, 1332.
Acetoacetanilide, 708.
Acetoacetic acid, phenylhydrazine salt of the hydrazone of, 162.
Acetoacrylic acid, diiodo-, 1179.
—— —— perchloro-*β*-, 1186.
—— oxime, 1179.
—— —— iodo-, 1179.
Acetocitric acid, TRANS., 1005.
—— —— reduction of, TRANS., 1009.
Acetodiketohexamethylenedicarboxylic acid, 586.
Acetoisobutyl alcohol, TRANS., 71.
—— bromide, TRANS., 72.
Acetoisobutyric acid, *β*-, derivatives of, 74.

Acetol ethyl ether, 954.
Acetomesitylene, action of hydroxylamine hydrochloride on, 314.
Acetonaphthalide, α-, physiological action of, 366.
Acetonaphthalide, β-, 4:1-bromiodo-, TRANS., 767.
—— 1:4-chlorobromo-, TRANS., 768.
Acetone, chlor-, 1425.
—— detection of, 1032.
—— diamido-, 952.
—— hydrazone, TRANS., 787.
—— symmetrical dichloro-, preparation of, 952.
—— thiocyan-, 1425, 1426.
Acetonediacetic acid, 432.
Acetonedicarboxylic acid, action of diazobenzene on, 161.
—— —— action of phenylhydrazine on, 162.
—— —— reduction of, 147.
Acetonedisazobenzene, 710.
Acetoneresorcinol, 1312.
Acetonitrile, di- and tri-chloro-, polymerides of, 1291.
Acetophenone mercuric chloride, 829.
—— sodium derivative of, 170.
Acetophenonethiophenylhydrazone, 1326.
Acetopiperone, 873.
Acetoprotocatechone, 61.
Acetothienone mercuric chloride, 829.
Acetothienoneoxalic acid, 154.
—— —— oxime of, 304.
Acetothiosulphuric acid, salts of, 1419.
Acetotoluidide, meta-, parabromo-, 1201.
—— —— parachloro-, 1201.
Acetotoluidide, ortho-, action of sulphuryl chloride on, TRANS., 1042.
—— —— derivatives of, 838.
—— —— nitrobromo-, 1207.
Acetotoluidide, para-, action of sulphuryl chloride on, TRANS., 1042.
—— —— 2:6-dibromo-, 175.
—— —— metachloro-, 450.
—— —— 6:3-nitrochloro-, 173.
Acetovanillone, 59.
—— derivatives of, 61.
—— synthesis of, from guaiacol and acetic acid, 61.
Acetovanillonephenylhydrazine, 61.
Acetoveratrone, 61.
Acetoxime, action of diazobenzene on, 1080.
—— action of hydrocyanic acid on, 1196.
Acetoxime-β-naphthylsulphone, 334.
Acetoximeparatolylsulphone, 334.
Acetoximephenylsulphone, 334.
Acetoximes, 333.
—— physiological action of, 1506.
Acetoxydichloropyridone, 449.
Aceto-xylide, parachlorometa-, 1202.
Acetoxytetramethylenecarboxylic acid, TRANS., 45.
Acetyl, magnetic rotation of substances supposed to contain, TRANS., 800.
Acetyl-α-acetaldoxime, PROC., **1892**, 136.
Acetylacetone, magnetic rotation of, TRANS., 813, 840, 844.
—— refractive and dispersive powers of, TRANS., 846.
Acetylacrylic acid, dibromo-, 302.
—— —— trichloro-, action of hydroxylamine on, 1203.
Acetylamidoguanidine salts, 1297.
Acetylamidoisophthalic acid, 1464.
Acetylbenzamide, 982.
Acetylbenzeneazoacetone, 977.
Acetylbenzenehydrazo-orthocresol, 975.
Acetylbenzoylmethyl cyanide, 451.
Acetylbenzylmetaxylidine, 1320.
Acetylbenzylorthotoluidine, 48.
Acetylbutylchloraldoxime, 34.
Acetylcampherylphenylhydrazine, 1481.
Acetylchlorantiglyoxime, 694.
Acetylchlorophenols, isomeric, 308.
Acetyldinitrocarvacrol, 309.
Acetyldiorthotolylhydrazine, 843.
Acetyldiparatolylhydrazine, 844.
Acetyldiphenylhydrazine, 710, 843.
Acetylene, formation of, from bromoform, 421.
—— formation of, in the interior of a luminous flame, TRANS., 325.
—— higher homologues of, 1163.
—— metallic derivatives of, PROC., **1892**, 109.
—— origin of, in flames, PROC., **1892**, 47.
—— silver and copper compounds of, 1416.
Acetylenedicarboxylic acid, diiodo-, 431.
Acetylenic hydrocarbons, action of organic acids on, 1064.
Acetyl-β-ethylthiophen, 830.
Acetylfenchylamine, 1230.
Acetylfluorescin, 1319.
Acetylglycerol, dichloro-, 289.
Acetylguvacine, 740.
Acetylhydrindigotin, 480.
Acetylhydroximidoacetonitrile, 816.
Acetylindigotin, 480.
Acetylisoeugenol, 46.
Acetylmetachlorobenzeneazoparacresol, 975.
Acetylmetachlorobenzenehydrazoparacresol, 975.
Acetylmethylphenyltetrahydroquinazoline, 81.

Acetyl-β-methylthiophen, 830.
—— bromo-, 830.
Acetylmethyltrimethylenecarboxylic acid, oxime of, Trans., 70.
—— —— preparation of, Trans., 69.
Acetyl-β-naphthylglycocine, 1342.
Acetyl-α-naphthylhydrazine, 509.
Acetyl-α-naphthylthiocarbizine, 510.
Acetylnicotenylamidoxime, 207.
Acetylorthohomoparahydroxybenzonitrile, 320.
Acetylorthotolylglycocine, 1334.
Acetylorthotolylhydrazine, 843.
Acetylortho-xylene, 1 : 2 : 4-, production of, from camphor, Proc., 1892, 54.
Acetylpæonol, 59. 845.
Acetylparabromodiphenylhydrazine, 982.
Acetylparabromophenylhydrazine, 982.
Acetylparachlorobenzeneazoparacresol, 974.
Acetylparachlorobenzenehydrazoparacresol, 974.
Acetylparachlorothiophenol, 308.
Acetylparethoxyphenylhydrazine, 1081.
Acetylparahomosalicenylamidoxime, 319.
Acetylparahomosalicylonitrile, 318.
Acetylparatolueneazoparacresol 974.
Acetylparatolylglycocine toluidide, chlor-, 1336.
Acetylparatolylhydrazine, 844.
Acetylphenoldisazotoluene, 976.
Acetylphenoxyethane, *aa'*-, 811.
Acetylphenylhydrazine, chlor-, 844.
Acetylphenylmethylhydroisopyrazolone, 635.
Acetylpropionyl, preparation of, 426.
Acetylquinaldine, para-, 1488.
Acetyltetrachlorocrotonic acid, dichloro-, 1462.
—— —— trichloro-, 1463.
Acetylthiocarbimide and aldehyde-ammonia, Trans., 530.
Acetylvanillonitrile, 318.
Acherontia atropos, blood of, 648.
Acid amides, mixed, 982.
Acids, affinity coefficients of, 1269.
—— amido-, action of hydriodic acid on, 38.
—— and bases, study of the chemical neutralisation of, by means of their electrical conductivities, 2.
—— astringent, estimation of, in wine, 246.
—— bibasic organic, thermochemistry of, 395, 1140.
—— fatty, action of iodine on the silver salts of, 1301.
—— —— action of, on olefines, 1162.
—— —— dry distillation of silver salts of, 37, 293, 811.
Acids, fatty, estimation of resin in admixture with, 389, 546.
—— —— higher, action of bromine on, 695.
—— —— polybasic, synthesis of, 41.
—— free, estimation of, 539.
—— —— in spirits, estimation of, 387.
—— influence of, on the velocity of the hydrolytic action of yeast, Trans., 940.
—— isodynamic, Proc., 1892, 103.
—— ketonic, behaviour of, towards sodium hydrogen sulphite, 148.
—— mechanical determination of the boiling points of, 1039.
—— monobasic, existence of acid or basic salts of, in very dilute solution, 110.
—— polybasic, electrolytic conductivity of, 1145.
—— of butter, 1113.
—— organic, affinity-coefficients of, and their relation to chemical constitution, 266.
—— —— determination of the affinity of, 37.
—— —— dissociation constants of, Trans., 696.
—— —— influence of boric acid on the electrical conductivity of aqueous solutions of, 257, 1265.
—— standard, use of potassium hydrogen tartrate for titrating, 525.
—— unsaturated, 812, 956.
—— —— conversion of, into their stereochemical isomerides by soda, 297.
—— —— decomposition of the dibromides of, by warm water and dilute alkalis, 959.
—— —— oxidation of, 956.
—— velocity of reaction in mixtures of isohydric and non-isohydric solutions of, 936.
Acidyl sulphides, 300. 581.
Aconine, Trans., 393.
—— action of methyl iodide on, Trans., 403.
—— conversion of, into aconitine, Trans., 401.
—— crystalline salts of, Trans., 399.
—— decomposition products of, Trans., 402.
—— distillation of, with baryta, 1255.
—— hydrochloride, crystalline, preparation of, Trans., 397.
—— properties of, Trans., 400.
Aconite, alkaloids of, Trans., 385, 395.
—— preparations, assay of, 392.
Aconitic acid, anhydro-derivatives of, Trans., 1003.

Aconitic acid, conversion of acetanhydrocitric acid into, TRANS., 1007.
—— —— dissociation constant of, TRANS., 707.
—— anhydride, TRANS., 1009.
—— —— action of ammonia on, TRANS., 1010.
Aconitine, 1254, TRANS., 390.
—— conversion of aconine into, TRANS., 401.
—— hydrolysis of, TRANS., 396.
—— methiodide, TRANS., 403.
—— methohydroxide, TRANS., 404.
—— reaction for, 756.
Aconitum napellus, alkaloïds of true, TRANS., 385.
Acridine, homologues of, 342.
Acridinemethylium hydroxide, 881.
Acridine-series, action of alkalis on the alkyl iodides of, 879.
Acridone, 1086.
—— derivatives of, 1223.
Acridonesulphonic acid, 3-, 1223.
Acrylic acid, diiodo-, 431.
Action at a distance, 956, 1149.
—— —— —— of aqueous solutions on water vapour, 936.
Adenine, 219, 220, 890.
—— bromination of, 221, 890.
—— bromo-, 890.
Affinity coefficients of acids, 1269.
—— —— of alkyl bromides and iodides, 1289.
—— —— of organic acids and their relation to chemical constitution, 266.
—— of organic acids, determination of, 37.
—— residual chemical, theory of, as an explanation of the physical nature of solutions, 559.
Agrostemma githago, sapotoxin from, 350.
Air vitiated by respiration, 1502.
Albumin, ash free, 645.
—— decomposition of, 515.
—— detection of, in urine, 667, 928.
—— egg, crystalline, 515.
—— formation of furfuraldehyde from, 1433.
—— new, from protoplasm, 86.
—— oxidation of, in presence of sulphur, 741.
Albumins, transformations of, 362.
Albumone, 225.
Albumoses, salicylsulphonic acid as a test for, 552.
Alcohol, detection of higher alcohols in, 1379.
—— estimation of, 1529.
—— is, eliminated by the milk? 365.
—— indirect estimation of, 543.
Alcohol, oxidation of, by permanganate, 1529.
—— Röse's process for the estimation of, 1031.
—— solutions, dilute, cryoscopy of, 1045.
Alcoholic fermentation, influence of oxygen and concentration on, TRANS., 360.
—— function, primary, value of the, 799.
—— —— tertiary, value of, 1066.
Alcohols, higher, detection of, in spirits of wine, 1379.
—— —— in spirits, estimation of, 387.
—— mechanical determination of the boiling points of, 1039.
—— polybasic, thermochemistry of, 763.
—— primary, direct synthesis of, 27.
—— tertiary, oxidation of, 28.
Aldeacids, 696.
Aldehyde. See Acetaldehyde.
Aldehyde, tetracarbon, presence of, in brandy, 810.
Aldehyde-ammonias, compounds of thiourea and thiocarbimides with, TRANS., 509.
Aldehydes, action of sodium on, 169.
—— action of zinc and ethyl chloracetate on, 1300.
—— aromatic, reduction of, 167.
—— bromo-, formation of, by the action of bromine on alcohols of the ethyl series, 809.
—— colour reaction of, with aromatic nitro-compounds, 1263.
—— condensation of, with azo-compounds, 854.
—— condensation of, with benzoylpiperidine, 1364.
—— fatty, condensation of, with dicyanophenylhydrazine, 596.
—— occurrence of acetyl derivatives in the urine of animals after ingestion of, 1504.
—— sodium nitroprusside as a reagent for, 924.
Aldehydic oxygen, estimation of, 546, 1530.
Aldol, preparation of, 1423.
Aldoximeacetic acids, configuration of, 1069.
Aldoximes, action of acetic anhydride on, 1174.
—— configuration of, 1174.
—— conversion of, into nitriles, 1174.
—— molecular transformations of, 163.
Alimentary canal, absorption of water from, 1258.
—— —— disinfection of the, 226.
Alizarinamide, β-, preparation of, 864.

Alkali carbonate, normal, detection of, in hydrogen alkali carbonate, 1130.
—— combined, in soap, estimation of, 384.
—— hydroxides, estimation of, 526.
Alkaline earth metals, direct combination of nitrogen with, 566.
Alkaline earths, action of sulphur and water on, 770.
—— —— characteristics of, 17.
Alkalis, action of sulphur on, 770.
—— influence of, on the hydrolytic action of yeast, TRANS., 936.
—— standard, use of potassium hydrogen tartrate for titrating, 525.
Alkaloïd from chrysanthemum flowers, 84.
—— from *Corydalis tuberosa*, TRANS., 244, 605.
—— from Javan coca leaves, 361.
Alkaloïds, free, estimation of, and of their molecular weights, 666.
—— influence of, on the germination of seeds, 228.
—— of *Belladonna*, 1498.
—— of *Berberis*, 641, 1498.
—— of *Berberis aquifolium* and *B. vulgaris*, 641.
—— of *Lupinus albus*, 892.
—— of the Areca nut, 737.
—— of the root of *Corydalis cava*, 1366.
—— of the Solanaceæ, 213.
—— of true *Aconitum napellus*, TRANS., 385.
—— reactions of, with potassium platinothiocyanates, 287.
Alkyl and acidyl sulphides, 300, 581.
—— bromides and iodides, affinity coefficients of, 1289.
—— halides and alcoholic potash, velocity of reaction between, 399.
—— —— halogenation of, 577, 1414.
—— iodides, preparation of, TRANS., 717.
—— phenylcarbamates, action of nitric acid on, 711.
Alkylacetonedicarboxylic acids, 148.
Alkylcamphors, preparation of, 72.
Alkylcyanocamphors, 1344.
Alkylorthotoluidines, paramido-, 1078.
Allanite from Gyttorp, Sweden, 1409.
Allocinnamic acid, condensation of, with phenols, 848.
—— —— formation of, from phenylpropiolic acid, 848.
Allotropic states of some elements, 405.
Alloxanhydrazone, 442.
Alloys, change of voltaic energy of, during fusion, 254.
—— estimation of gold, tin, and cadmium in, 1030.
Alloys, metallic, electrolytic preparation of, 394.
—— micrographic analysis of, 1399.
Allyl cyanide, constitution of, 27.
—— fluoride, action of halogens on, 800.
—— phenylamidoacetate, 468.
—— sodionitro-, 1062.
—— sodium thiosulphate, 1418.
Allylacetic acid, oxidation of, 958.
Allylcarbaminesodiocyamide, 703.
Allyldithiobiuret, α-, 704.
Allylethylsuccinic acids, 697.
Allylformamidine bisulphide, 292.
Allylfurfurylthiocarbamide, 43.
Allylisobutylthiocarbamide, symmetrical, 702.
Allylmethylsuccinic acids, 697.
Allylmelhylthiohydantoïn, 151.
Allylnitrolic acid, 1063.
Allylthiocarbamide, action of bromine on, TRANS., 545.
Allylthiohydantoïn, 151.
Allyltrimethylammonium hydroxide, 905.
—— —— derivatives of, 950.
—— salts, 949.
Alum, detection of, in wines, 1522.
Alumina, volumetric estimation of, 535.
Aluminium, action of certain liquids on, 687, 1281.
—— action of chlorine and of bromine on, 118.
—— action of mercuric cyanide dissolved in water and in organic solvents on, 797.
—— action of nitric acid on, 1403.
—— analysis of, 1130.
—— and iron, estimation of, by the Glaser method, 755.
—— —— estimation of, in the presence of phosphoric acid, 755.
—— and its alloys, assay of, 535.
—— commercial, assay of, 102, 535.
—— condition of, in cast iron, 19.
—— direct estimation of, in iron and steel, 102.
—— estimation of, in phosphates, 536.
—— hydroxide, colloïdal solution of, TRANS., 154.
—— in mineral waters, 1287.
—— occlusion of hydrogen by, 567.
—— phosphate, action of ammonium citrate on, 1127.
—— —— estimation of, 1522.
—— potassium fluoride, 1162.
—— specific heat of, 673.
—— —— —— and latent heat of fusion of, 1281.
—— suitability of, for domestic purposes, 687, 1281,
—— sulphide, 943.

Amalgams, electrolytic estimation of metals as, 753.
Amanita pantherina, toxic principle of, 232.
Amber, so-called, of Cedar Lake, Canada, 573.
Amethylcamphophenolsulphone, action of nitric acid on, 999.
Amethylcamphophenolsulphonic acid, action of nitric acid on, 999.
Amides, aromatic, action of trimethylene chlorobromide on, 1491.
—— dehydration of, in contact with diphenyl-derivatives, 617.
Amidines, 51.
—— action of nitric acid on, 951.
Amido-acids, action of hydriodic acid on, 38.
—— influence of, on gastric digestion, 742.
Amidoazobenzene, action of aniline hydrochloride on, 492.
Amido-groups in organic bases, method of determining the number of, Proc., **1892**, 133.
Amidosulphonic acid, 700.
Amidoximes, 135, 317.
—— action of benzenesulphonic chloride on, 460.
Amines, aromatic, action of trimethylene chlorobromide on, 1491.
—— —— conversion of, into chlorine derivatives of the hydrocarbons, 705.
—— —— isomeric change in the synthesis of, 44.
—— fatty, unsaturated, 30, 578.
—— primary, preparation of, by means of potassium phthalimide, 157.
—— tertiary aromatic, action of arsenic chloride on, 1321.
Ammonia, action of magnesium on, 409.
—— alcoholic solutions of, 1049.
—— excretion of, 365.
—— in the atmosphere and rain water of the tropics, 381, 909.
—— reduction of nitric acid to, by the galvanic current, 403.
Ammonio-copper ammonium cyanide, 420.
Ammonium barium imidosulphonate, Trans., 966.
—— calcium imidosulphonate, Trans., 968.
—— chloride, action of, on silicates, at its dissociation temperature, 772.
—— —— influence of ammonia on the solubility of, 276.
—— diaminechromium thiocyanate, 798.
—— dithionate hydrochloride, 13.
—— ethyl sulphate, 700.
Ammonium fluoroxyhypovanadate, 787.
—— fluoroxyvanadates, 785.
—— imidosulphonates, Trans., 946.
—— isobutyl sulphate, 701.
—— manganese chloride, 781.
—— methyl sulphate, 700.
—— nitrate, explosion of, 683.
—— nitride, 113.
—— orthotolylimidodiacetate, 1335.
—— pentasodium imidosulphonate, Trans., 961.
—— pyrosulphate, Trans., 948.
—— salts, direct absorption of, by plants, 229.
—— sodium hydrogen imidosulphonate nitrate, Trans., 962.
—— stannibromide, 121.
—— sulphate, formation of, by burning coal gas, 1389.
—— —— mineralising influence of, 1399.
—— tetraminechromium thiocyanate, 799.
Ampelochroic acids, α-, β-, and γ-, 1242, 1243.
Amphiglyoxime, chlor-, 693.
Amyl alcohol, formation of, from starch by a bacterium, 90.
—— alcohols, action of bromine on, 809.
—— phenylamidoacetate, 468.
Amylacetylene, normal, 1064.
Amylamine, ε-chlor-, 717.
—— hydrogen diaminechromium thiocyanate, 1000.
Amylamylenamine, 804.
Amylenehydroxynaphthaquinone, Trans., 611.
Amylfurfurylcarbamide, 43.
Amylmethylacetylene, 1065.
Amyloid, vegetable, 803.
Amyrilines, 288.
Amyrinoxime, α-, 290.
Amyrins, α- and β-, hydrocarbons from, 288.
—— —— —— oxidation products of, 290.
Amyrone, α-, 290.
Amyrone, β-, 290.
Amyroneoxime, β-, 290.
Anæmia, tropical, 363.
Analcime as rock forming material, 1413.
Analgen, 1104.
Analysis, combination of wet and dry methods in, 100.
—— elementary, new drying apparatus for, 657.
—— gravimetric, simple and rapid method of, 524.
—— of liquids, application of capillary phenomena to, 236.

Analysis, organic, new method of, 753.
—— quantitative, new methods of, 103, 538.
—— —— use of bromic acid in, 910, 1027.
—— —— use of iodic acid in, 1027.
Anemonic acid, 1241.
Anemonin, 1241.
Anemoninic acid, 1241.
Angelic acid, constitution of, 1304.
Angostura bark, constituents of, 642.
Angosturin, 744.
Anhydrobenzenesulphoneorthamidobenzamide, 334.
Anhydrocinnamaldehydanisidine, 1195.
Anhydro-derivatives of citric and aconitic acids, Trans., 1033.
Anhydroecgonine, constitution of, 360.
Anhydroformaldehydaniline, 1190.
Anhydrometanitrocinnamaldehydanisidine, 1195.
Anhydrotricarballylic acid, 41.
Anhydrovaleraldehydaniline, 1193.
Anilacetone, isonitroso-, 985.
Anilbenzoïn, action of hydrocyanic acid on, 1196.
Anilcyanamide, 1323.
Anilic acid, decomposition products of, 834.
—— acids, substituted, crystalline forms of the sodium salts of, Trans., 581.
Anilides, acid, colour reactions of, 709.
—— isoanilides and their analogues, 705.
Anilidobenzenemetadisulphonic acid, 333.
Anilidobenzenesulphonic acid, metanitro-orsho-, 332.
—— —— metanitropara-, 331.
Anilidobromopianic acid, 1209.
Anilidocinnoline, 1494.
Anilidodiphenylpyrrolone, 1002.
Anilidoisobutyric acids, 1338.
Anilidoisovaleramide, α-, 1192.
Anilidometanitrobenzophenone, ortho-, 336.
—— para-, 336.
Anilidometasulphobenzoic acid, ortho-, 333.
—— —— para-, 333.
Anilidometamidobenzenesulphonic acid, ortho-, 332.
—— —— para-, 332.
Anilidonaphthoic acid, β-, 1476.
—— anilide, β-, 1476.
Anilidonitrobenzanilide [2 : 5], 326.
Anilidoparadiketohexene, pentachlor-, 448.
Anilidopropionic acid, α-nitroso-, 1456.
Anilidopropionic acid, β-, 1342.
Anilidotetraphenylpyrroline, 995.
Anilidotrinitrotoluene, sodium derivative of, 1218.
Aniline, action of trimethylene chlorobromide on, 1491.
—— and furfuraldehyde, condensation of, 1452.
—— hydrogen diaminechromium thiocyanate, 1000.
—— nitrodibrom-, 1205.
—— orthonitro-, preparation of, 837.
—— platinothiocyanate, 287.
—— refractive power of, at different temperatures, Trans., 301.
—— thionylthio-, 1326.
Anilineazo-α-naphthol, ethyl and methyl ethers of, 862.
Aniline-black, dyeing with, in the dry way, 323.
Anilinesulphonic acids, parachlor- and parabrom-, constitution of, Proc., 1892, 40.
Anilpyruvic acid, condensation of, 54.
Animal economy, action of oxalic acid and its derivatives on the, 1018.
—— —— change of sulphanilic acid into sulphanilocarbamic acid in the, 903.
—— organism, mechanism of the production of urea in, 89.
Anisodus luridus, alkaloïds of, 232.
Anisoïl, dinitrodiamido-, 596.
—— sulphonic acids derived from, Proc., 1892, 90.
—— tetramido-, 596.
Anniversary meeting, Trans., 474.
Anodonta cygnea, blood of, 648.
Ant oil, composition of, 942.
Anthracene, action of nitric acid on, Trans., 865.
—— action of nitric acid on, in presence of acetone, Trans., 871.
—— action of nitric acid on, in presence of ether, Trans., 872.
—— action of nitric acid on, in presence of trimethylcarbinol, Trans., 870.
—— benzyl nitrate, Trans., 871.
—— isobutyl nitrate, Trans., 867.
—— propyl nitrate, Trans., 866.
Anthranilamide, dichlor-, 335.
Anthrax, chemical pathology of, 744.
—— in man, 1117.
Anthrole, nitro-, Trans., 869.
Anthrone, nitro-, Trans., 865, 868.
—— —— action of alcoholic potash on, Trans., 869.
Anthyllis vulneraria, composition of, 522.
Antiglyoxime, chlor-, 694.
Antimonious chloride, solution of, in saturated solutions of sodium chloride, 413.
—— compounds, estimation of, 526.
Antimonite from Felsöbánya, 1054.

Antimonite from Magurka, 1054.
Antimony, action of nitric acid on, 1402.
—— arsenic and tin, detection of, 918.
—— —— —— separation of, Trans., 424.
—— double halogen salts of, 788.
—— electrolytic detection of, 541.
—— estimation of, 242.
—— hydrosulphide, Trans., 133.
—— lowering of the freezing point of bismuth by, Trans., 896.
—— lowering of the freezing point of cadmium by, Trans., 901.
—— lowering of the freezing point of lead by, Trans., 908.
—— minerals, assay of, 918.
—— separation of, from arsenic, 541.
—— sodium alloy, 773.
—— sulphide, colloïdal solutions of, Trans., 142.
—— thiophosphate, 413.
Antipyrine, action of sodium and carbonic anhydride on, 1106.
—— alcohol of, 708, 730, 1106.
—— nitro-, 730.
—— paralkyloxy-derivatives of, 1080.
Apionyloximidoacetic acid, 328.
Apoatropine, 1255.
Apocinchonine, 1253.
Apple tree leaves, analyses of, 1372.
Arabinose, fermentation of, with *Bacillus ethaceticus*, Trans., 737.
—— physiological action of, 1506.
—— reactions of, 290.
—— thermochemistry of, 763.
Arabitol, thermochemistry of, 764.
Arctic Ocean, water from the, 1287.
Areca nut, alkaloïds of the, 737.
Arecaïdine, 739.
Arecoline and its salts, 738.
Argentic disodium imidosulphonate, Trans., 976.
Aristolochia argentina, alkaloïd from, 894.
—— *reticulata*, volatile oil from, 70.
Aristolochin, 874.
Aristolochine, 894.
Aromatic compounds, unsaturated, action of nitrous acid on, 447.
Arsenic acid, separation of, from mercury, sodium, chlorine, and nitric acid, 530.
—— —— thio-, and thioxyarsenic acid, separation of, 1519.
—— —— volumetric estimation of, 1519.
Arsenic, allotropic states of, 405.
—— antimony and tin, separation of, Trans., 424.
—— cyanide, 1164.
—— direct estimation of, in minerals and metals, 530.
Arsenic, electrolytic separation of gold from, 920.
—— estimation of, by oxidation with the electric current, 752.
—— estimation of, in wall paper, 382.
—— hydrosulphides, Trans., 127.
—— lowering of the freezing point of bismuth by, Trans., 894.
—— lowering of the freezing point of cadmium by, Trans., 899.
—— lowering of the freezing point of lead by, Trans., 906.
—— separation of antimony from, 541.
—— testing metallic iron for, 1030.
Arsenious acid, volumetric analysis with, 1374.
—— compounds, estimation of, 526.
—— sulphide, colloïdal solutions of, Trans., 140, 144, 160.
Arsines, tertiary, action of benzal chloride on, 984.
Artemisia absinthium, absinthin from, 1240.
Artichoke, Jerusalem, composition and cultivation of, 1024.
—— —— cooked, composition of, Trans., 227.
Asaprol, 1116.
Asbestos, use of, in filtration, 751.
Asbolin, 1312.
Ascharite, a new borate, 792.
Asparagine, decomposition of, in the human body, 904.
—— influence of carbohydrates on the accumulation of, in plants, 91.
Aspergillus niger, action of, on fumarates and maleates, 820.
Asphalt in Utah and Colorado, 21.
Asphyxia, effect of, on the glycolytic and saccharific powers of the blood, 517.
Assimilation of atmospheric nitrogen, 1507.
—— of carbohydrates, 742.
Astacus fluviatilis, blood of, 648.
Astragalus, analyses of, 522.
Astrophyllite, new analyses of, 22.
Atmosphere, estimation of organic matters in, 542.
—— estimation of the carbonic anhydride of, 533.
—— of the Tropics, ammonia in, 381, 909.
Atomic weight and magnetism, 672.
—— —— of boron, Trans., 650.
—— —— of cadmium, 1397.
—— —— of cobalt, 1159.
—— —— of nickel, 1158.
—— —— of oxygen, 1388.
—— —— of palladium, Trans., 745.
—— weights, relations between, 938.

Atropa belladonna, alkaloïds of, 231.
Atropamine, 1256.
Atropine, detection of, 1534.
—— nitro-, 1014.
Atropine, ψ-, 891.
Aurantiol, 868.
Auric sulphide, properties and reactions of, 280.
Aurin, acetyl derivatives of, 1319.
Aurintricarboxylic acid, 855.
Autocatalysis, 1270.
Axinite, formula of, 125.
Azimidazoles, 313.
Azines of the uric group, 70.
Azobenzene, dinitroso-, 1079, 1198.
—— —— preparation of, 1321.
—— —— so-called, 889.
—— nitronitroso-, reduction of, 1322.
Azobenzenedisulphonamide, 973.
Azobenzenemetachlorophenylhydrazine,
—— trinitro-, 456.
—— trinitronitroso-, 455.
Azobenzeneorthocarboxylic acid, 67.
—— —— parachlor- and parabrom-, 68.
Azobenzenephenylhydrazine, nitro- and chloronitro-derivatives of, 455.
Azo-colours, alkylated, of the naphthalene series, reduction of, 862.
Azo-compounds, condensation of aldehydes with, 854.
—— —— mixed, 710.
—— —— nitroso-, constitution of, 1453.
—— —— oxidation of, 48.
—— —— reduction products of, 839.
Azodibenzylamine, ortho-, 316, 890.
Azodicarbonamide, 1298.
—— preparation of, 1430.
Azodicarbonamidine salts, 1297.
Azodicarboxylic acid, 1429.
Azo-group, intramolecular formation of, 316.
—— —— substitution of, for ketonic oxygen, 451.
Azoimide, 112.
—— action of, on living organisms, 90.
—— heat of formation of, 261.
—— thermochemistry of, 933.
Azoisatin, 451.
Azomethylquinoline, 729.
Azonium bases, 1246.
—— compounds, 1108.
Azotoluenedisulphonamide, 1468.
Azoximes, 135, 317.
Azoxymethylethylisoxazole, 79.
Azoxymethylquinolines, 727, 729.
Azoxyorthodichlorostilbene, para-, 444.
Azoxyphenetoïl, para-, 159.

B.

Bacillus amylozymicus, 90.
—— *ethaceticus*, fermentation of arabinose with, TRANS., 737.
—— —— fermentation of mannitol and dextrose with, TRANS., 442.
—— *ethacetosuccinicus*, fermentation of mannitol and dulcitol by, TRANS., 254.
—— —— morphological characterisation of, TRANS., 275.
—— of malignant œdema, action of, on carbohydrates and on lactic acid, 91.
—— *radicicola*, accumulation of atmospheric nitrogen in cultivations of, 1019.
Bacteria, soluble colouring matters produced by, in distilled medicinal waters, 907.
Bacterium which ferments starch and produces amyl alcohol, 90.
Balance, modified, for rapid weighing, 270.
Balance sheet of the Chemical Society, from March 19th, 1891, till March 18th, 1892, TRANS., 484.
—— —— of the Research Fund, from March 19th, 1891, till March 18th, 1892, TRANS., 485.
Barium acetothiosulphate, 1419.
—— ammonium phosphotungstates, 1160.
—— and calcium, separation of, 915.
—— carbide, 685.
—— estimation of, 539.
—— hydrogen imidosulphonate, TRANS., 965.
—— hypophosphate, 403.
—— imidosulphonate, TRANS., 964
—— isophthalate, composition and crystalline form of, 179.
—— mercury imidosulphonate, TRANS., 977.
—— nitride, 566, 776.
—— oxide, non-existence of dimorphism in, 17.
—— permolybdate, 1160.
—— peroxide, action of, on metallic salts, 408.
—— —— use of, in analysis, 1031.
—— barium persulphate, 12.
—— potassium imidosulphonate, TRANS., 967.
—— separation of, from calcium, 100.
—— sodium imidosulphonate, TRANS., 967.
—— strontium and calcium, separation of, 660.
—— sulphamate, TRANS., 966.
—— thiocyanate, water of crystallisation of, 1418.

Barium, volumetric estimation of, 1521.
Barium-group, analysis of, 660.
Bark of trees, calcium oxalate in the, 1370.
Barks, estimation of gallotannic and gallic acids and tannin in, 390.
Barley, distribution and condition of iron in, 1509.
Barytes from Missouri, 792.
Basalt of the Stempel, near Marburg, 126.
Bases and acids, study of the chemical neutralisation of, by means of their electrical conductivities, 2.
—— organic, action of ethyl cyanacetate on, 1071.
—— —— chloriodides of, 1356.
—— —— method of determining the number of imido-groups in, PROC., 1892, 133.
—— Schiff's, 1189.
Baths, hot, influence of, on the excretion of nitrogen and uric acid from the human system, 1503.
Batteries, gas, E.M.F. of, 393.
—— secondary, theory of, 1381.
Beans, broad and haricot, cooked, composition of, TRANS., 227.
Bebeerine, reactions of, 756.
Beer and beer wort, estimation of maltose, dextrose, and dextrin in, 248.
Beeswax, analysis of, 1034.
—— assay of, for vegetable wax, 551.
—— detection of resin in, 923.
—— examination of, 251.
Beet diffusion chips, frozen and unfrozen, composition of, 1512.
Beet juice, organic acids in, 231.
Beetroot, cooked, composition of, TRANS., 227.
Behenolic acid, action of reducing agents and of bromine on, 812.
—— —— diiodo-, 471.
—— —— tetrachloride of, 1427.
—— anilide, 1427.
—— diphenylhydrazide, 1427.
—— phenylhydrazide, 1427.
Belladonna, alkaloïds of, 1498.
—— subsidiary alkaloids of, 1255.
—— wild, alkaloïds of, 231.
Benzal chloride, condensation of with benzene, 719.
Benzalamidoguanidine, 1297.
Benzaldehyde, action of, on 2 : 6-lutidine, 1360.
—— action of sodium on, 171.
—— action of zinc and ethyl chloracetate on, 1300.
—— and ethyl cyanacetate, condensation of, 1086.
—— hydrazone. TRANS., 788.
—— orthamido-, condensation of, 1106.
Benzaldehyde, parabromometanitro-, 336.
—— paranitro-, change of, in the system, 1504.
Benzaldehydephenylhydrazone, orthamido-, 1106.
Benzaldiphenylmaleïde and its derivatives, 179, 483.
—— bromo-, 483.
Benzaldiphenylmaleïmidine, 484.
—— nitro-, 487.
Benzaldiphenylmaleïnethylimidine, 484.
Benzaldoxime, synorthochloro-, 1200.
Benzaldoximes, orthochloro-, 1199.
—— α- and β-paranitro-, 163.
Benzalglucoheptitol, 1168.
Benzalhydrazine, 456.
Benzalsemicarbazide, 1297.
Benzamide 2 : 5-amidonitro-, 326.
—— orthamido-, action of sulphonic chlorides on, 334.
—— —— thio-derivatives of, 54.
—— physiological action of, 367.
—— thio-, action of iodine on, 1109.
Benzamidoxime benzyl ether, 464.
Benzene, action of acetic and benzoic chlorides on halogen derivatives of, 337.
—— and dipropargyl, 1436.
—— chloro-, action of bromine on, TRANS., 111.
—— chloropentabromo-, 155.
—— condensation of, with benzal chloride, 719.
—— constitution of, 1211.
—— dichlorotetrabromo-, 155.
—— dinitro-, physiological action of, 366.
—— dinitrochloro-, action of, on polyhydric phenols, 310.
—— flames, experiments on, TRANS., 209, 210.
—— hexabromide, preparation of, TRANS., 110.
—— hexachloride, chloro-, α- and β-modification of, TRANS., 103.
—— —— —— action of potassium cyanide on, TRANS., 108.
—— —— reduction of, 594.
—— iodation of, 1310.
—— metadinitro-, 704.
—— —— bromination of, 155.
—— —— reduction of, 595.
—— penta-, derivatives of, 596.
—— ring, displacement of halogen atoms in the, 335.
—— rule for determining whether a given mono-derivative of, shall give a meta-di-derivative or a mixture of ortho- and para-di-derivatives, TRANS., 367.

Benzene, symmetrical trinitro-, bromination of, 155.
—— tetrachlorodibromo-, 155.
—— triamidotrinitro-, symmetrical, reduction of, 1198.
—— tribromonitro-, 1182.
—— unsymmetrical tetrachloro-, properties of, TRANS., 109.
Benzeneazocyanocamphor, 1343.
Benzeneazo-β-naphtholdisulphonic acid, oxidation of, 48.
Benzeneazo-α-naphthylglycocine, 191.
—— —— meta-, ortho-, and para-nitro-, 1100.
Benzeneazoparacresol, metachloro-, 975.
—— parachloro-, 974.
Benzeneazoresorcinol, para-, 977.
Benzeneazo-β-tolylnaphthylamine, 1476.
Benzenediazoacetanilide, 458.
Benzeneindone, 341.
Benzenemetadisulphonic acid, amido-, 333.
Benzenes, iodo-, 1310.
—— nitro-, heats of combustion and formation of, 4.
—— —— displacement of the nitro-group in, by chlorine or bromine, 306.
Benzenesulphinic acid, parabromo-, 1091.
Benzenesulphonamides, and mixed secondary amines, 64.
Benzenesulphonebenzylamide, 65.
Benzenesulphonemethylethylamide, 64.
Benzenesulphoneorthamidobenzamide and its derivatives, 334.
Benzenesulphoneorthamidobenzomethylamide, 335.
Benzenesulphoneorthamidobenzophenylamide, 335.
Benzenesulphoneorthamidobenzoylphenylhydrazine, 335.
Benzenesulphoneorthomethamidobenzamide, 335.
Benzenesulphoneorthotoluidine, 65.
Benzenesulphoneparaphenetidine, 65.
Benzenesulphonepiperidine, 65.
Benzenesulphonic acid, metanitro-orthamido-, 331.
—— —— metanitroparamido-, 331.
—— —— nitroso-, preparation and salts of, 475.
—— acids, chloramido- [1 : 2 : 4 and 1 : 4 : 2], 182.
—— —— chloronitro- [1 : 2 : 4 and 1 : 4 : 2], 182.
—— —— halogenated, action of ammonia and aniline on, 331
—— chloride, parabromo-, 1220.
—— —— parachloro-, 1220.
Benzenesulphonitramide, 850.
Benzenethiosulphonic acid, reactions of, 478.
Benzenylamidethoxime, action of nitrous acid on, 323.
Benzenylamidine picrate, 705.
—— salts, 51.
Benzenylchloroxime, 463.
—— paranitrobenzyl ether, 464.
Benzenylchloroximeglycollic acid, 465.
Benzenyldiamidoacetone, 952.
Benzenylethoxime salts, 323.
Benzenylhydrazoximamidobenzylidine, preparation of, 461.
Benzenylimidosulphonic acid, 701.
Benzenylnitrotoluylenamidine, 1197.
Benzenylorthohomosalicenylazoxime, 320.
Benzenylparahomosalicenylazoxime, 319.
Benzhydroxamic acid, stereoisomeric derivatives of, 461.
Benzide, diamidosulpho- and its derivatives, 1093.
Benzidine, polymethylene bases from, 1223.
Benzidinedisulphonamide, 974.
Benzidinemetacarboxylic acid, 68.
Benzidylbromopianic acid, 1210.
Benzile, action of aniline on, 1470.
—— action of, on triamidodiphenylamine, 1109.
—— action of paramidodimethylaniline on, 855.
—— sodium derivative of, 171.
Benziledianil, 1470.
Benzileoximeanil, 1470.
Benzileoximehydrazone, 1471.
Benzileoximeparatolyl, 1470.
Benzileoximes, 1470.
—— Claus' theory of the, 186, 598.
Benzilideneamidocarbazole, 616.
Benzilidenebenzidine, nitro-derivatives of, 854.
Benzimidazoles, 631, 632.
Benzimido-β-chlorethyl ether, 1331.
Benzofurfuran derivatives, synthesis of, 608.
Benzoic acid and benzaldehyde, condensation of, 339.
—— —— 2 : 5-bromonitro-, amide, anilide, and chloride of, 326.
—— —— 2 : 4-chloronitro-, chloride, amide, and anilide of, 327.
—— —— impurities in commercial, 604.
—— —— iodoso-, 1460.
—— —— nitrosulpho-, 479.
—— —— parabromo-, iodation of, 714.
—— —— parabromometanitro-, salts of, 714.
—— —— separation of salicylic acid from, 1532.

Benzoic acids, amido-, reactions of, 847, 1380.
—— —— bromo-, bromination of, 171.
—— —— dibromo-, 1205.
—— —— dichloro-, 1206.
—— —— halogenated nitro-, action of ammonia and aniline on, 326.
Benzoïn, action of paradiamidodimethylaniline on, 855.
Benzonitrile, action of benzoic chloride on, 1183.
—— action of sulphuric anhydride on, 713.
—— compound of, with hydrogen cyanide, 1449.
Benzonitriles, dibromo-, 1205, 1206.
—— dichloro-, 1206.
Benzoparadifurfuran-α-dimethyl-β-dicarboxylic acid, paradichloro-, 610.
Benzophenone, diparabromodimetanitro-, 336.
—— diparabromometanitro-, 336.
—— imido-, hydrochloride, 339.
—— orthbromo-, 992.
—— orthobromometanitro-, 336.
—— parabromometanitro-, 336.
—— paradinitro-, 1460.
—— paramido-, oximes of, 489.
—— paramidometanitro-, 336
—— paramidometanitroparabromo-, 336.
—— sodium compound of, 170.
Benzophenone-derivatives, oximes of, 487.
Benzophenoneparamidobenzoic acid, 340.
Benzotoluidide, paranitro-, 839.
—— thionitro-, 839.
Benzoyl compounds, preparation of, 604.
Benzoylacetamide, 325.
Benzoylacetone, acids from the dicyanhydrin of, 1471.
—— action of paramidodimethylaniline on, 855.
—— magnetic rotation of, Trans., 831, 861.
Benzoylaconine, formation of, Trans., 401.
Benzoylamidocarbazole, 616.
Benzoylbenzamide, metanitro-, 52.
Benzoylbenzeneazoacetone, 977.
Benzoylbenzenehydrazo-orthocresol, 975.
Benzoylbenzylmetaxylidine, 1320.
Benzoylbenzylparatoluidine, 313.
Benzoylchlorophenols, isomeric, 308.
Benzoyldihydroxyanhydroecgonine, derivatives of, 1016.
Benzoyldiorthotolylhydrazine, 843.
Benzoyldiphenylhydrazide, 711.
Benzoyldiphenylhydrazine, 843.
Benzoylformorthotoluidide, 1442.
Benzoylglutarimidoxime, 138.
Benzoylhydrochlorocarvoxime, 1348.
Benzoylimidopropionylethyl cyanide, derivatives of, 450.
Benzoylisoeugenol, 46.
Benzoyllimonene nitrosochloride, 1348.
Benzoylmetachlorobenzeneazoparacresol, 975.
Benzoylmetachlorobenzenehydrazoparacresol, 975.
Benzoylmethyltrimethylene, Trans., 86.
Benzoylmethyltrimethylenecarboxylic acid, Trans., 84.
—— —— oxime of, Trans., 85.
Benzoyl-α-naphthylhydrazine, 509.
Benzoylnicotenylamidoxime, 207.
Benzoylnitrosoresorcinol ethyl ether, 45.
Benzoylorthamidophenylacrylic acid, 881.
Benzoylorthotolylcarbamide, 832.
Benzoylorthotolylhydrazine, 843.
Benzoyloscine, 1498.
Benzoylparabromanilide, 460.
Benzoylparachlorobenzeneazoparacresol, 975.
Benzoylphenylazomethylene, reactions of, 451.
Benzoylphenyldiiodomethane, 451.
Benzoylpropionic acid, oximes of, 1202.
Benzoyl-α-pyridyllactic acid, 76.
Benzoyl-β-pyridyllactic acid, 78.
Benzoylpyruvic acid, oxime of, 304.
Benzoylretene, 1205.
Benzoylsuccinimidoxime, 137.
Benzoylsulphobenzamidinic anhydride, 713.
Benzoyltetrahydroquinaldine, nitroderivatives of, 882.
—— oxidation of, 881.
Benzoylthiocarbimide and aldehydeammonia, Trans., 532.
Benzoyltrimethylene oxime, Trans., 86.
Benzoylxylide, 491.
Benzyl alcohol, paramidorthochloro-, 445.
—— —— paranitrorthochloro-, 445.
—— bromide, paranitrorthochloro-, derivatives of, 444.
—— dinitrosylorthochloro-, 1200.
—— ethyl ether, paranitrorthochloro-, 445.
—— hydroxycamphocarboxylate, 74.
—— imidodicarbothioxylate, 844.
—— imidodiphenylthiocarbamate, Proc., 1892, 97.
—— metaxylyl ketone, 338.
—— methyl ether, paranitrorthochloro-, 444.

Benzyl orthotoluate, action of sodium on, Proc., **1891**, 167.
—— orthotolylcarbamate, 832.
—— ortho-xylyl ketone, 338.
—— paraxylyl ketone, 338.
—— phenylimidophenylbenzylthiocarbamate, Proc., **1892**, 97.
Benzylacetanilide, orthamido-, 80.
Benzylacetoglutaric acid, 963.
Benzylacetomethylamide, diorthonitro-, 218.
—— orthamido-, 218.
Benzylamidoacetic acid, benzylamide of, 1458.
Benzylamidosulphonic acid, 476.
Benzylamine, action of carbonyl chloride on, 312.
—— and furfuraldehyde, condensation of, 1452.
—— di-iodo-, 1449.
—— diorthonitro-, 218.
—— hydrogen malate, action of heat on, 820.
—— orthonitro-, 217.
Benzylaniline, paranitrorthochloro-, 445.
Benzylbenzenylamidine, 1110.
Benzylbenzyl ortho-xylyl ketone, 338.
Benzylbenzylhydroxylamine, nitro-, oxidation of, 1456.
Benzylborneols, 73.
Benzylbornylamine, 1238.
Benzylcamphor, 73.
Benzylcamphoroxime, 73.
Benzyl-δ-caprolactone, γ-, 963.
Benzylcarbamide, orthonitro-, 218.
Benzylchrysaniline, 1095.
Benzylcinchonidine, 1251.
Benzyldihydroxycinchotenidine, 1251.
Benzydihydroxycinchotenine, 1250.
Benzyldiphenylmaleïde and its derivatives, 484.
Benzyldiphenylmaleïmidine, 484.
Benzyldiphenylmaleïnethylimidine, 485.
Benzyldiphenylthiourea, Proc., **1892**, 97.
Benzylethylparatoluidine, 313.
Benzylethylphenylthioureas, isomeric, Trans., 540.
Benzylfenchylamine, 1239.
Benzylfumaramic acid, 821.
Benzylfumarimide, 821.
Benzylfurfuraldoxime, 1434.
Benzylhydroxyanthranol, 346.
Benzylhydroxycaproic acid, salts of, 963.
Benzylhydroxydiphenylmaleïde, 483.
Benzylhydroxylamine, β-chloro-, 1200.
—— β-dichloro-, 1199.
—— β-metanitro-, 51.
Benzylhydroxylamines, oxidation of, 316.
Benzylidenebornylamine, 1238.
Benzylidenecinchonic acid, 1489.
Benzylidenecinchoxinic acid, 1489.
Benzylidenecyanacetic acid, 1340.
Benzylidenediphenylsulphone, 612.
Benzylidenefenchylamine, 1239.
Benzylidene- 2 : 6-lutidine, 1360.
—— reduction of, 1361.
Benzylideneorthamidophenol, 196.
Benzylideneparamidophenol, 1451.
Benzylideneparanitraniline, 1194.
Benzylidenepinylamine, 997.
Benzylidenepiperazine, 211.
Benzylidenethiophenylhydrazone, 1326.
Benzylisobenzaldoxime, metanitro-, 50.
Benzylisobutylcarbamide, 312.
Benzylisometanitrobenzaldoxime, intramolecular change of, 50.
Benzyliso-orthochlorobenzaldoxime, orthochloro-, 1199.
Benzylisoparanitrobenzaldoxime, intramolecular change of, 50.
Benzylmalamic acid, 822.
Benzylmalimides, α- and β-, 821.
Benzylmalonic azimide, Trans., 796.
—— phenylhydrazide, Trans., 796.
Benzylmetanitrophenylcarbamide, 312.
Benzylmetaxylidine, 314.
—— nitro-, 1320.
Benzylmetaxylidinesulphonic acid, 1320.
Benzylmethylamine, diorthonitro-, 218.
Benzylmethylparatoluidine, 313.
Benzyl-α-naphthylcarbamide, 312.
Benzylnitrobenzylhydroxylamine, oxidation of, 1456.
Benzylœnanthaldoxime, 1436.
Benzylorthotoluidine, 48.
Benzylorthotoluidinesulphonic acid, 313.
Benzylparachlorodeoxybenzoïn, 1227.
Benzylparaditolylcarbamide, 1083.
Benzylparatoluidine, 313.
—— hydrochloride, orthamido-, 734.
Benzylparatolylcarbamic chloride, 1083.
Benzylparatolylsemithiocarbazide, Trans., 1022.
Benzylpentoxazoline, μ-, 215.
Benzylphenylhydrazine, orthamido-, 1455.
—— orthonitro-, 1455.
—— phosphenite, 1325.
Benzylphenylhydrazone, thionyl-, 1324.
Benzylphenylmethylcarbamide, 312.
Benzylphenylsemithiocarbazide, Trans., 1021.
Benzylpiperidylcarbamide, 312.
Benzylquinoline-γ-carboxylic acid, betaïne of, 1488.
Benzylsulphonethiobenzylmethylmethane, 613.
Berbamine, 641.
Berberine, 1498.

Berberine, action of bromine on, 1498.
—— pyridinecarboxylic acids from, 1357.
—— salts, 642.
Berberis alkaloïds, 641, 1498.
Berberis aquifolium, constituents of, 641.
—— *vulgaris*, alkaloïds of, 641.
Berberonic acid, 1357.
Bergamot oil, 868, 1235.
—— —— crystalline products from, 349.
—— —— stearoptene of, 71.
Bergapten, the stearoptene of bergamot oil, 71.
Beronic acid, 1357.
Beryllium hypophosphates, 404.
Betaïne in cotton-seed foods, 380.
Betel oil, composition of, 833.
Betelphenol, 833.
Biazolones, 508.
Biguanide, preparation of, from guanidine, 737.
Bile during inanition, 225.
—— ox, presence of myristic acid in, 1114, 1503.
—— putrefaction of, 518.
Birotation of sugars, influence of ammonia on, 1419.
Bis-α_1-keto-γ_1-methyljulolidyl, 497.
Bismuth, action of nitric acid on, 1403.
—— and cadmium, separation of, by means of bromine vapour, 385.
—— and lead, separation of, by means of bromine vapour, 540.
—— chloride, dissolution of, in a saturated solution of sodium chloride, 122.
—— double halogen salts of, 788.
—— estimation of, 539.
—— estimation of, in silver slags, 919.
—— hydrosulphide, attempts to prepare, TRANS., 132.
—— lead, tin, and cadmium, separation of, 754.
—— liquid, thermal expansion of, 259.
—— lowering of the freezing point of cadmium by, TRANS., 904.
—— lowering of the freezing point of lead by, TRANS., 910.
—— lowering of the freezing point of, when alloyed with other metals, TRANS., 888, 892.
—— pure, 20.
—— salicylate, 122.
—— separation of, from lead, 385.
—— sodium alloy, 773.
—— tribromide, action of hydrogen phosphide on an ethereal solution of, 279.
Bismuthic acid, 413, 688.
Bismutite, 793.
Bis-1 : 2 : 3-phenylbenzoylmethylpyrazolone, 146.
Biurets, thio-, 703.
Bleaching powder, estimation of active chlorine in, 1374.
Blende, separation of lead, silver, and zinc in, 1378.
Blood, action of carbon bisulphide on, 1520.
—— coagulation of the, 87, 1112.
—— detection of, 1369.
—— disappearance of sugar from the, 363.
—— dissolved nitrogen in, 1257.
—— estimation of the glycogen in, 89.
—— fermentation of, 900.
—— formation of sugar from peptones in, 1502.
—— glycolysis in, 900.
—— glycolytic power of, 364.
—— of a living mammifer, absorption of carbonic oxide by, 743.
—— of Europeans living in the tropics, sp. gr. of, 363.
—— of invertebrates, 648.
—— of leucæmic patients, peptones in the blood of, 519.
—— of *Pinna squamosa*, 1016.
—— of the crustaceæ, blue colouring matter of, 898.
—— peptone, gases of, 363.
—— serum, human, new proteïd from, 224.
—— sugar in, 743.
—— toxic action of, 228.
—— variations of the glycolytic and saccharific powers of, in asphyxia and diabetes, 517.
Blood-ash, influence of nutrition on the composition of, 225.
Body, human, decomposition of fibrin, gelatin, peptone, and asparagine, in the, 904.
Boehmeria, composition of, 1511.
Boiler incrustation, composition of a, 17.
Boiling point curves for the normal paraffins, 947.
—— points of acids and alcohols, mechanical determination of, 1039.
—— —— of compounds with complex terminal substitution, mechanical determination of, 1039.
—— —— of compound of simple terminal substitution, mechanical determination of, 948.
—— —— of normal isomeric ethereal salts of the fatty series, calculation of, 260.
—— —— of paraffin derivatives, calculation of, 797.

Boiling points of solutions of metallic chlorides, TRANS., 340.
Boleite, 123.
Boletus edulis and *B. aurantiacus*, distribution of sugars in, 519.
Bone-black, iron in, 1053.
Bones, fossil, of various ages, proportion of fluorine in, 1413.
—— influence of various salts on the composition of, 647.
—— recent and fossil, fluorine in, 1161.
Borates, metallic, 404, 565.
Boric acid, action of, on germination, 651.
—— —— and mannitol, freezing points of aqueous solutions of, 263.
—— —— estimation of, 384.
—— —— influence of, on the electrical conductivity of dilute alcoholic solutions of organic acids, 1265.
—— —— presence of, in the products of the soil, 93.
Borneocamphene, 624, 625.
Borneol, constitution of, 865.
Bornyl ethyl ether, 200, 348.
—— methyl ether, 348.
—— methylene ether, 200, 348.
Bornylamine tartrate, 1238.
Boron, action of, on organic halides, 1316.
—— amorphous, preparation of, 681, 682.
—— —— properties of, 1153.
—— atomic weight of, TRANS., 650.
—— bromide, combination of ammonia with, 771.
—— —— preparation of, TRANS., 655.
—— iodide, 1154.
—— —— combination of ammonia and of hydrogen phosphide with, 771.
—— nitride, action of methyl alcohol on, 1311.
—— pentasulphide, 1394.
—— phosphides, 115, 272, 273.
—— phosphodi-iodide, 114.
—— phosphoiodide, 115.
—— trisulphide, 1392.
Bran, distillation of, with lime, PROC., **1892**, 138.
Brandy, presence of a tetracarbon aldehyde in, 810.
Brasileïn, derivatives of, 502.
Brasilin, oxidation of, 502.
Brassidic acid and erucic acid, stereometric relations of, 429, 812, 1427.
—— —— bromo- and chloro-, 429.
—— —— dichloro-, 1427.
—— —— dichloride, 429.
—— phenylhydrazide, 1428.
Braunite from Sweden, 1404, 1405.
Breithauptite from Sarrabus, Sardinia, 790.
Bromanilic acid, action of halogens on 834.
—— —— crystalline form of the sodium salt of, TRANS., 582.
Bromic acid, use of, in quantitative analysis, 910, 1027.
Bromides, estimation of, 527.
—— of potassium, sodium, and hydrogen, action of sulphuric acid on, TRANS., 94.
Bromine and chlorine, detection of, in presence of iodine, 1514.
—— —— relative orienting effect of, PROC., **1892**, 40.
—— carriers of, 155.
—— chlorine, and iodine, exchange of, between inorganic and organic haloïd compounds, 574.
—— —— —— separation of, 1027.
—— direct combination of, with metals, 118.
—— heat of combination of, with magnesium, 762.
—— vapour, separation of metals of the hydrogen sulphide group by means of, 754.
Bromochloranilic acid, crystallography of the sodium salt of, TRANS., 584.
Bromoform, formation of acetylene from, 421.
—— preparation of, from acetone and sodium hypobromite, 126.
Brookite, 1055.
Brushwood, food value of, 1511.
Bulbocapnine, 1366.
Bunsen burner for spirit, 1386.
Bunte's salt, preparation and properties of, 799.
Burettes, improvements in, 1027.
Burner, new laboratory, 768, 1386.
Butaldehydes, condensation of, with aniline, 1192.
Butane, absorption-coefficient of, in water, 1043.
Butanetricarboxylic acid, 42.
Butter, acids of, 1113.
—— detection of coco nut fat in, 391.
—— detection of margarin in, 1034.
—— estimation of foreign fats in, 1532.
—— estimation of free acids in, 924.
Butyl alcohol, normal, action of bromine on, 809.
—— bromides, bromination of, 1414.
—— chlorides, chlorination of, 1415.
Butylamine, δ-chloro-, 131.
Butylbenzene, action of aluminium chloride on, 1309.
Butylchloralacetamides, 1067.
Butylchloralaldol, 695.
Butylchloralbenzamides, 1067.
Butylchloraldoxime, 33.
Butylchloralformamides, 1067.

Butylenes, monobromo-, 127.
Butylidenaniline, 1192.
Butylmetaxylene, tertiary, derivatives of, 718.
Butylmethylacetylene, 1064.
Butylparisopropyltoluene, ortho-, 985.
Butylphenol, paratertiary, 44.
Butyltoluenesulphonic acid, nitration of, 718.
Butylxylenesulphonic acid, nitration of, 718.
Butyramide, αβ-dibromo-, 27, 33.
Butyric acid, α-amido-, derivatives of, 1338.
—— —— αβ-dibromo-, 27, 33.
—— —— β-sulpho-, 424.
Butyrolactone, action of sodium ethoxide on, 813.
—— hydrolysis of, 1303.

C.

Cabbage, cooked, composition of, TRANS., 227.
Cadmium, action of nitric acid on, 1278.
—— and bismuth, separation of, 385.
—— and copper, separation of, 534.
—— and gold, compound of, TRANS., 914.
—— atomic weight of, 1397.
—— crystallisation of, 1398.
—— diaminechromium thiocyanate, 1002.
—— electrolytic separation of, from osmium and from nickel, 920.
—— fluorovanadite, 788.
—— fluoroxyhypovanadate, 787.
—— gold, and tin, estimation of, in alloys, 1030.
—— hydrosilicate, 1157.
—— hydrosulphide, TRANS., 129.
—— lead, tin, and bismuth, separation of, 754.
—— lowering of the freezing point of bismuth by, TRANS., 895.
—— lowering of the freezing point of lead by, TRANS., 907.
—— lowering of the freezing point of, when alloyed with other metals, TRANS., 888, 897.
—— mercuric cyanide, TRANS., 687.
—— mercuric thiocyanate, 10.
—— nitrate, basic, 1157.
—— oxide, action of hydrogen peroxide on, 1278.
—— sulphides, 778.
—— use of, in assaying gold, 919.
Cadmium-silver alloy, analyses of, TRANS., 913.
Cæsium antimony chloride 788.
—— bismuth chloride, 789.
—— bromiodides, 773.
—— chloriodides, 773.
—— chlorobromides, 773.
—— chlorobromiodide, 773.
—— compounds, extraction of, from carnallite, 1395.
—— hydroxide, properties of, 274.
—— manganese chloride, 781.
—— reduction of, 274.
—— properties of, 274.
—— tribromide, 773.
—— triiodide, 773.
Calcium and barium, separation of, 100, 915.
—— and strontium nitrates, separation of, by means of amyl alcohol, 915.
—— —— separation of, as chromates, 914.
—— chlorate, rate of decomposition of, by heat, 1275.
—— chloride, boiling points of solutions of, TRANS., 340.
—— —— solutions, dilute, cryoscopy of, 1045.
—— chromate, solubility of, in dilute alcohol, 914.
—— estimation of, in gun-cotton, 1520.
—— estimation of, in phosphates, 534.
—— estimation of small quantities of, 914.
—— hydrogen imidosulphonate, TRANS., 968.
—— imidosulphonate, TRANS., 968.
—— iron, and manganese, separation of, 916.
—— metaborate, 404.
—— nitrate, basic, 1157, 1276.
—— —— cryoscopy of dilute solutions of, 1045.
—— nitride, 566.
—— oxalate in the bark of trees, 1370.
—— phosphate, crystalline, 407.
—— phosphates, solubility of, in solutions of phosphoric acid, 684.
—— potassium thiosulphate, 12.
—— salts, effect of, on the coagulation of the blood, 87, 1112.
—— —— estimation of, in syrup and sugar products. 1377.
—— sodium imidosulphonate, TRANS., 968.
—— strontium, and barium, separation of, 660.
—— volumetric estimation of, 1521.
Calorimetric bomb, modified form of, 260.
—— —— use of compressed oxygen in, 673.

Camphene, 868.
—— and camphoric acid, 868, 1240, 1481.
—— constitution of, 858, 868.
Camphenol, properties of, 199.
Camphenylparatolylhydrazine, 1481.
Camphenylphenylhydrazine, 1481.
Camphocarboxylic acid, 201.
Camphoic acid, constitution of, 866.
Campholamine, 1345.
Campholenic acid, 1237.
—— —— oxidation of, 1237.
—— —— reduction of, 1238.
Campholic acid, 1345.
—— —— action of potassium hypobromite on the amide of, 1345.
—— —— constitution of, 866.
Campholonitrile, 1345.
Campholyl isocyanate, 1345.
Campholylamine, 1346.
Campholylcarbamide, 1345.
Camphonitrile, 1237.
Camphor, action of sodium alkyloxides on, 72.
—— and fenchone series, 1236.
—— behaviour of, in mixtures of two solvents, 1137.
—— constitution of, 203, 724, 865, 869.
—— dibromo-, reactions of, 1343.
—— production of, 1 : 2 : 4-acetylorthoxylene from, Proc., **1891**, 188; **1892**, 54.
Camphoric acid, action of various reagents on, 1100.
—— —— and camphene, 868, 1240, 1481.
—— —— constitution of, 202, 348, 500, 627, 865, 869, 1041, 1100, 1346, 1347; Trans., 1096.
—— —— function of, 1346.
—— —— hydrazones of, 1481.
—— —— methyl salts of, Trans., 1088.
—— —— new acid from, Proc., **1892**, 55, 68.
—— —— thermochemistry of, 1041.
Camphor-group, 724, 1343.
Camphorone, 626; Proc., **1891**, 188; **1892**, 54.
Camphors and their compounds with chloral, physiological action of, 227.
Camphosulphophenols, ethylnitroketone and acetylnitroketone from, 1085.
—— nitroketone from, 999.
Cancer pagurus, blood of, 648.
Cantharene, 1480.
Cantharidin, action of phenylhydrazine on, 999.
Caoutchouc, spontaneous conversion of isoprene into, 1482.
Capillary constants of salts at their melting points, 7.
Capillary phenomena, application of, to the analysis of liquids, 236.
Caprylaldehyde, constitution of, 293.
Caproic acid, dibromo-, decomposition of, 960.
Capryl iodide, action of, on trimethylamine, 806.
Capsaicin, 1263.
Capsicum annuum, fruit of, 1263.
Carbamic acid, occurrence of, in horse's urine, 518.
Carbamide, action of phenylhydrazine on, 1323.
—— crystallisation of, by sublimation, 1309,
—— volatility of, 1309.
Carbamide. See also Urea.
Carbamido-acids, 827.
Carbaminethioacetophenone, 1317.
Carbamine-β-thiolactic acid, 440.
Carbanilidothiophenantialdoxime, 1435.
Carbanilidothiophensynaldoxime, 1435.
Carbaniltolylurethane, thio-, 600.
Carbazacridines, 617.
Carbazides, semithio-, bisubstituted, Trans., 1012.
Carbazole, 616, 1466.
—— amido-, 616.
—— behaviour of, towards carbonyl chloride, 167.
—— diamido, synthesis of, 480.
Carbin cyanide (methyl cyanide), 132.
Carbodiparatolylamide, stereoisomerism of, 1452.
Carbodiphenylimide, stereoisomerism of, 1452.
Carbohydrates, action of the bacillus of malignant œdema on, 91.
—— assimilation of, 742.
—— classification of the, 1066.
—— colour reactions of, 664.
—— estimation of, in vegetable products, 248.
—— influence of, on the accumulation of asparagine in plants, 91.
—— of putrefying human urine, 226.
—— production of acetic acid from 1421.
—— thermochemistry of, 763.
Carbon, action of, on sodium sulphate in presence of silica, 565.
—— action of, on sulphurous anhydride at high temperatures, 681.
—— allotropic states of, 405.
—— amorphous, allotropism of, 945.
—— and silica, action of, on chromic fluoride, 20.
—— and silicon, compounds of, 1050.
—— bisulphide, detection of in toxicological cases, 1520.
—— —— flame, experiments on, Trans., 216.

Carbon bisulphide, toxic action of, 1520.
—— bivalent, 1438.
—— chlorobromides, 771.
—— deposited from coal gas flames, Proc., 1892, 46.
—— diiodide, 1291.
—— estimation of, in iron, 913, 1030.
—— examination of various forms of, 1273.
—— oxysulphide, preparation of, 15.
—— peculiar form of, 565.
Carbon-chains, closed, synthetical formation of, Trans., 36, 67.
Carbonic anhydride, absorption-coefficient of, in water and in alcohol, 1044.
—— —— atmospheric, estimation of, 533.
—— —— combined and free, apparatus for the estimation of, 531.
—— —— in the urine, 649.
—— —— influence of oxygen on the separation of, in the lungs, 1369.
—— —— new isothermal curves for, 3.
—— —— reactions of, at high pressures, 274.
—— —— supersaturated aqueous solutions of, 1274.
Carbonic anhydride-regenerator-gas, reconversion of heat into chemical energy by production of, 673.
Carbonic oxide, absorption coefficient of, in water, 1043.
—— —— absorption of, by the blood of a living mammifer, 743.
—— —— action of, on iron and manganese, 568.
—— —— and oxygen, influence of steam and other gases on the combustion of, 274.
—— —— detection of traces of, 99.
—— —— estimation of, 1128.
Carbonic-oxide-hæmoglobin, solutions of, Trans., 159.
Carbonylchloroplatinite, derivatives of, 352.
Carbonylphenyl-β-naphthylthiocarbamide, 984.
Carbonylphenylparatolylthiocarbamide, 984.
Carboparatoluidobenzantialdoxime, 1435.
Carboparatoluidobenzsynaldoxime, 1435.
Carboparatoluidofurfursynaldoxime, 1434.
Carborthotoluidothiophensynaldoxime, 1436.
Carbostyril, bromopseudochloro-, 630.
Carboxyantiglyoxime, 816.
Carboxy-α-hydroxycinnamic lactone, ortho-, 857.
Carboxyphenylglyceric acid, ortho-, δ-lactone of, 857.
Carboxypimelic acid, α-, 428.
Carboxysynglyoxime, 816.
Carnallite, extraction of rubidium and cæsium compounds from, 1395.
Carrots, cooked, composition of, Trans., 227.
Carvacrol, behaviour of, towards reducing agents, 157.
—— bromamido-, 595.
—— bromo-derivatives of, 156.
—— derivatives of, 309, 1312.
—— preparation of, 1311.
Carvene, constitution of, 1350.
Carvole, derivatives of, 499.
Cascarin, 1483.
Cassia, oil of, estimation of cinnamaldehyde in, 924.
Catechol in the urine of hydrophobic rabbits, 1115.
—— sodium derivatives of, 1184, 1185.
—— thermochemistry of, 764.
Cauliflower, cooked, composition of, Trans., 227.
Celery, cooked, composition of, Trans., 227.
Celestine from Scharfenberg, 1406.
Cell, Latimer Clark standard, practical form of, 669.
Cell. See also Battery, Galvanic Cell.
Cell-membranes, vegetable, 907.
Cellulose, 693.
—— benzoates, 693.
—— colloïdal solutions of, Trans., 156.
—— dissolving enzyme in the digestive tract of certain animals, search for a, Trans., 352.
—— estimation of, 923.
—— nitrates, action of alkaline solutions on, 692.
—— production of acetic acid from, 1421.
—— sulphite-, dextrose from, 801.
—— thermochemistry of, 764.
Cellulose-gum, 129.
Celluloses, 907.
Cereals, development of, 1119.
Cerium-earths, 1400.
Cerium-group, separation of the metals of, 686.
—— spectroscopic researches on, 686.
Cerotic acid, bromo-, 1302.
Cerous oxide, reaction for, 239.
Cetyldeoxybenzoïn, 1224.
Chabasite from the Faroe Islands, 1408.
Change, interval of, 1145.
Cheese, estimation of fat in, 392.
Chemical action at a distance, 268, 269.
—— phenomena, application of the second law of thermodynamics to, 3.
—— —— at very low temperatures, 1138.

Cherry laurel, occurrence of mannitol and sorbitol in the fruit of, 908.
Chestnut-wood tannin, 716.
Chloral, action of hydroxylamine on, 699.
—— bornylate, 228.
—— condensation of, with paraldehyde and ketones, 694.
—— menthylate, 228.
Chloralacetone, 694.
Chloralacetophenone, 695.
Chloralaldol, 695.
Chloraldoxime, 33.
Chloralhydroxylamine, 699.
Chloralimide, 134.
—— dimolecular, 134.
—— trimolecular, 134.
Chloranilic acid, action of halogens on, 834.
—— —— and bromanilic acid, compound of, Trans., 574.
—— —— crystallography of the sodium salt of, Trans., 583.
Chlorates, iodometric estimation of chloric acid in, Trans., 87.
Chlor-α-dibromhydrin, action of zinc-dust and alcohol on, 1293.
Chloric acid, estimation of, 236.
—— —— iodometric estimation of, in chlorates, Trans., 87.
—— —— volumetric estimation of, 1375.
Chlorides, estimation of, 527.
—— metallic, action of magnesium on, 777.
—— —— physical properties of solutions of, Trans., 339.
Chlorine, active, in bleaching powder, estimation of, 1374.
—— and bromine, detection of, in presence of iodine, 1514.
—— —— relative orienting effect of, Proc., 1892 40.
—— and oxygen, reaction of, with hydrogen, 1147.
—— bromine, and iodine, exchange of, between inorganic and organic haloïd compounds, 574.
—— —— —— separation of, 1028.
—— direct combination of, with metals, 118, 401.
—— measurement of light intensity by the expansion of, 253.
—— separation of, from mercury and phosphoric and arsenic acids, 530.
—— use of platinous chloride as a source of, Trans., 445.
Chlorite, manganiferous, from Harstigen Mine, Sweden, 1411.
Chlorite-group, theories of the structure of, 794.
Chlorites, constitution of, 125.
Chloritoïd from Michigan, 793.
Chlorocruorin, 1256.
Chloroform, action of alkali sulphides on, 421.
—— impure, physiological action of, 744.
—— peculiar phenomena in the solidification of, 1138.
Chlorophyll, 1355.
—— crystals of, 1356.
—— influence of phosphoric acid on the formation of, 1261, 1272.
—— substances accompanying, in leaves, 746.
Chlorophyllane, nature of, 1136.
Chlorophyllic extracts, analysis of, 1136.
—— substances of the pericarp of the grape, 874.
Chlorosis, treatment of, with hydrochloric acid, 1117.
Cholesterol, estimation of, 248, 544.
—— vegetable, 1294.
Cholic acid, 741.
Choline, action of hydriodic and hydrobromic acids on, 808.
—— and neurine, relations between, 219.
—— derivatives of, 806. 905.
—— in cotton-seed foods, 380.
Chromammonium salts, 782.
Chromates, volumetric estimation of, 1375.
Chrome-iron-ore, analysis of, 1031.
—— decomposition of, 240.
Chrome-tourmaline from Maryland, 1057.
Chrome-yellows, analysis of, 663.
Chromic acid, Trans., 405.
—— —— estimation of, 103, 538.
—— anhydride, action of sulphur on, 770.
—— chloride, solutions of, Trans., 153.
—— hydrate, colloïdal solution of, Trans., 154.
—— hydrogen potassium pyrophosphate, 1053.
—— oxide, estimation of, 104.
—— sulphate, green, 411.
—— —— isomeric forms of, 411.
Chromite, analysis of, 1525.
Chromium ammonium thiocyanate, derivatives of, 798.
—— estimation of, in chromium-aluminium alloys, 1131.
—— estimation of, in steel, 538.
—— metallic, attempts to prepare, from chromic fluoride, 19.
—— salts, action of heat on solutions of, 571.
—— test for, 1133.
Chromium-bases, constitution of, 783.

Chromosulphuric acid and its salts, 783.
Chrysaniline, action of methyl iodide and hydroxide on, 1095.
—— azo- and alkyl compounds of, and the dyes therefrom, 1095.
Chrysanthemine, 84.
Chrysanthemum cinerariæfolium, constituents of the buds of, 349.
—— flowers, new alkaloïd from, 84.
Chrysidines, *α*- and *β*-, and their derivatives, 198.
Chrysophanic acid, 1354.
Cicuta maculata, examination of, 232.
Cincholine, 1492.
Cinchona alkaloïds, 1249.
—— —— alkyl derivatives of, 1012.
—— —— compounds of, with hydriodic acid, 83.
—— —— halogen derivatives of, 1010.
—— —— hydriodo-compounds of, 1363.
—— —— sulphonic acids of, 514.
Cinchonic acid, alkyl and alkylene derivatives of, 1488.
—— —— ethiodide, 1490.
—— —— ethobromide and ethochloride, 1489.
—— —— ethylbetaïne, 1490.
—— —— methobromide, methochloride, and methiodide, 1489.
—— —— methylbetaïne, 1489.
—— —— propobromide, 1491.
Cinchonidine benzyl salts, 1251.
—— compounds of, with hydriodic acid, 83.
—— ethiodides and methiodides, 1251.
Cinchonidinesulphonic acid, 515.
Cinchonine, 892.
—— action of hydriodic acid on, 514, 639.
—— chloride, 1011.
—— —— hydrochloro-, 1011.
—— compounds of, with hydriodic acid, 83.
—— dichloro-, 1011.
—— diethyl salts, 1252.
—— ethocyanide, 1251.
—— hydriodo-, salts of, 1363.
Cinchoxinic acid, alkylene derivatives of, 1488.
Cineolic acid, 1480.
—— —— constitution of, 866.
—— allylamide, 1480.
—— diethylamide, 1480.
—— paratoluidide, 1480.
—— phenylhydrazide, 1480.
—— piperidide, 1480.
Cinnamaldehyde, estimation of, in oil of cassia, 924.
Cinnamidiureïde, 57.
Cinnamene, condensation of, with phenols, 446.
Cinnamene, triiodo-, 470.
Cinnamenyloxazoline, *μ*-, 215.
Cinnamenylpentoxazoline, *μ*-, 215.
Cinnamic acid, condensation of, with hydrocarbons, 1228.
—— —— condensation of, with phenols, 848.
—— —— *β*-dibromo-, 1464.
—— —— *αβ*-dichloro-, 1464.
—— —— diiodo-, 470.
—— —— oxidation of, 986.
—— —— refractive power of, at different temperatures, TRANS., 306.
—— acids, isomeric *α*-bromo-, TRANS., 278.
—— —— stereoisomeric and polymeric, 469.
—— diphenylhydrazide, 981.
Cinnamon, oil of, 1509.
Cinnamylideneorthamidophenol, 1452.
Cinnamylideneparamidophenol, 1451.
Cinnamylphenylazimide, formation of, TRANS., 282.
—— imide of, TRANS., 283.
—— reduction of, TRANS., 284.
Cinnamyltetrahydroketonaphthaquinoxaline, 886.
Cinnamyltetrahydroketoquinoxaline, 886.
Cinnoline, chloro-, 1494.
—— derivatives of, 1494.
Citraconic acid, conversion of, into its isomerides by soda, 297.
Citrates, alkali, 149.
Citrazinic acid, TRANS., 1008.
Citric acid, 824.
—— —— anhydro-derivatives of, TRANS., 1003.
—— —— detection of tartaric acid in, 546.
—— —— dissociation constant of, TRANS., 708.
—— —— separation of malic acid from, 1531.
—— —— thermochemistry of, 763.
Citronellic aldehyde, 1068.
Citrus bergamia, stearoptene from the oil of, 71.
Clamps for gas analysis apparatus, 524.
Clay, chromiferous, from Brazil, 1057.
Clover, red, assimilation of free nitrogen by, 373, 374.
Cloves, oil of, valuation of, 250.
Coagulation and calcium salts, 1112.
—— of the blood, 87, 1112.
Coal, action of dilute nitric acid on, PROC., **1892**, 9.
—— formulæ for calculating the heating power of, 1143.
—— heats of combustion of products of the distillation of, 395.

Coal, valuation of, for use in steam boilers, 668.
Coal-dust explosions, lecture experiment to illustrate the phenomena of, TRANS., 414.
Coal-gas flames, carbon deposited from, PROC., **1892**, 46.
—— —— —— experiments on, TRANS., 205, 210.
—— —— —— formation of sulphuric acid in, 1374.
—— —— —— luminosity of, TRANS., 322.
—— —— formation of sulphuric acid and ammonium sulphate by burning, 1151, 1389.
Cobalt, action of nitric acid on, 1279.
—— action of nitric oxide on, 1152.
—— atomic weight of, 1159.
—— chloride, hydrates of, 569, 571.
—— —— vapour pressure of aqueous solutions of, 263.
—— —— variations in colour of, 569, 570.
—— detection of, 1525.
—— estimation of, in manganese ores, 917.
—— fluoride, 1160.
—— fluoroxyhypovanadate, 787.
—— mercuric thiocyanate, 10.
—— nitro-, 1390.
—— occlusion of hydrogen by, 567.
—— potassium fluoride, 782.
—— reactions of, 1132.
—— salts, action of alkaline polysulphides on, 537.
—— —— colour of solutions of, 278.
—— separation of iron from, 103.
—— separation of manganese from, 240.
—— sulphate, anhydrous, 941, 1283.
Cobalt-bases, constitution of, 783.
Cobra poison, 1118.
Cocaïne hydrogen diaminechromium-thiocyanate, 1001.
Coca leaves, Javan, alkaloïd from, 361.
Coco-nut fat, detection of, in butter, 391.
Codeïne, reactions of, 756.
Codeïne-violet, 360.
Coffee substitutes, analysis of, 1534.
Collidine, preparation of, 725.
Colloïd solutions, nature of, 766.
—— —— pedetic motions in relation to, PROC., **1892**, 17.
Colour and constitution of compounds, 561.
—— appearance of, in quinoline derivatives, TRANS., 789.
—— as an evidence of isodynamic change, PROC., **1892**, 103.
—— origin of, PROC., **1892**, 101, 103; TRANS., 789.
Colour-photometry, PROC., **1891**, 150.
Combustion, incomplete, analysis of the products of, 407.
—— of carbonic oxide and oxygen, influence of steam and other gases on, 274.
—— slow, of gaseous mixtures, 938.
Combustion-furnace, new, 1514.
Compounds, double, solubility of, 1047.
Compressibility and indices of refraction of liquids, relations between, 669.
—— of saline solutions, 766.
Concentration, effect of, on alcoholic fermentation, TRANS., 369.
Condensation and evaporation, spheres of, 1149.
Condenser, new, 400.
Conductivity. See Electrical Conductivity.
Condurangin, 1352.
Congo-red, colloïdal solutions of, TRANS., 156.
Constitution and colour, relation between, PROC., **1892**, 101, 103; TRANS., 789.
Contact, potential, differences of, 553.
Conyrine, oxidation of, 1104.
Copaiba, estimation of volatile oil in, 244.
Copiapite, 1408.
Copper, action of chlorine and of bromine on, 118.
—— action of nitric oxide on, 1152.
—— ammonium sulphate, 1399.
—— and cadmium, separation of, 534.
—— apparent variability of the electrochemical equivalent of, 105.
—— chloride, ammoniacal, action of potassium cyanide on, 1065.
—— —— measurement of the vapour pressures of solutions of, TRANS., 775.
—— —— solubility of, in various organic liquids, 558.
—— electrolytic detection of, 541.
—— electrolytic separation of mercury from, 239.
—— estimation of, by de Haen's (Brown's) method, 753.
—— estimation of, in aluminium, 1131.
—— formate, 140.
—— hydrosulphides, TRANS., 120.
—— lowering of the freezing point of bismuth by, TRANS., 893.
—— lowering of the freezing point of cadmium by, TRANS., 898.
—— lowering of the freezing point of lead by, TRANS., 905.
—— mercuric thiocyanate, 10.
—— nitrate, basic, decomposition of, by water, 1272.
—— nitride, supposed, 409.
—— nitro-, 1390.

Copper, nitrosonaphtholsulphonate 346.
—— occlusion of hydrogen by, 567.
—— oxalate, 1431.
—— —— and pyridine, compound of, 1431.
—— oxide, anhydrous, 1399.
—— permolybdate, 1160.
—— phosphides, 410.
—— precipitation of, by iron, 276.
—— red, estimation of sulphur in, 753.
—— reduced, retention of hydrogen and carbon by, 942.
—— sulphate, basic, 1399.
—— —— crystallised anhydrous, 941, 1399.
—— —— solutions, dilute, cryoscopy of, 1045.
—— sulphite, basic, 1051.
—— sulphites, 1051.
Copper. See also Cuprous.
Copper-glance, oxidation of, by the electric current, 239.
Cordierite as contact mineral, 1056.
Corn-cockle, metabolism in pigs fed on, 1018.
Corycavine, 1367.
Corydaline, 1366; TRANS., 244, 605.
—— action of hydrogen iodide on, TRANS., 609.
—— allyl iodide, TRANS., 249.
—— ethyl sulphate, TRANS., 607.
—— hydriodide, TRANS., 246.
—— hydrobromide, TRANS., 607.
—— methiodide, TRANS., 248.
—— platinochloride, TRANS., 247.
Corydalis cava, alkaloïds of the root of, 1366.
—— *tuberosa*, alkaloïd from, TRANS., 244, 605.
Coto bark, constituents of, 60, 873.
Cotonoleïc acid, 584.
Cotton plant, chemical study of, 1510.
—— —— feeding value of, 1510.
Cotton-seed foods, choline and betaïne in, 380.
—— oil, constituents of, 584.
—— products, 584.
Coumarin, derivatives of, 988.
—— thio-, and its analogues, 329.
Coumarone, reduction of, 1318.
Cream, estimation of fat in, 392.
Creatinine, estimation of, in urine, 1135.
—— influence of muscular work on the elimination of, 364.
Cresyl orthacetates, meta-, ortho-, and para-, 308.
Crocoïte, synthesis of, 792.
Crops, assimilation of phosphoric acid by, 233.
—— leguminous, sources of the nitrogen of, 367.
Crotonaldehyde, action of suphurous anhydride on, 424.
—— preparation of, 809, 1423, 1424.
Crotonaldoxime, 33, 580.
—— dichloro-, 34.
Crotonanilide, amido-, 965.
—— β-amido-, 708.
Crotonic acid, oxidation of, 957.
—— acids, bromo-, 961.
Crustaceæ, blue colouring matter of the blood of, 898.
Cryoscopic behaviour of dilute solutions, 8, 678, 1045.
—— determinations, 765.
Cryoscopy of cane-sugar solutions, 109, 678, 1046.
—— of dilute alcohol solutions, 1045.
—— of dilute calcium chloride solutions, 1045.
—— of dilute calcium nitrate solutions, 1045.
—— of dilute copper sulphate solutions, 1045.
—— of dilute ether solutions, 1045.
—— of dilute sodium chloride solutions, 1045.
—— of dilute urea solutions, 1045.
Cryptogams, assimilation of free nitrogen by, 370, 378.
Cryptopine and its derivatives, PROC., 1891, 166.
Crystallisation, water of, 581.
Crystals, artificial colouring of, 269.
—— influence of foreign substances on the form, purity, and size of, 937.
—— mixed, 1048.
—— —— formation of, 10.
—— —— solubility of, 265, 266, 560.
—— theory of the structure of, 572.
Cucumbers, cooked, composition of, TRANS., 227.
Cumarhydrin, para-, 873.
Cumenylacrylic acid, nitration of, 43.
Cumic acid, paradibromo-, 605.
Cumindiureïde, 57.
Cuminylanilide, 489.
Cumonitrile, propoxy-derivatives of, 595.
Cumylphosphinic acid, ψ-, 1085.
Cuprammonium acetobromide, 953.
—— oxalate, 1431.
—— oxide, 18.
Cupreïne, 1253.
—— behaviour of, with methyl iodide, 221, 892.
—— conversion of, into quinine, 1010.
Cuprodescloizite from Mexico, 1055.
Cuprous acetylide, 1416.
—— —— preparation of, 421.
—— iodide and ammonium thiosulphate, compounds of, 1157.
—— sulphite, 1052.

Current reversal, 759.
Curvature, the recognition of changes of, by means of a flexible lath, 767.
Cusparia trifoliata, constituents of, 642.
Cusparine, 643.
Cusparidine, 643.
Cyanacetophenone, action of hydroxylamine on, 324.
—— and its derivatives, 324, 845.
Cyanacetothienone, 304.
Cyanacetylaniline, 1072.
Cyanacetylbenzylamine, 1072.
Cyanides, condensation of, with ethereal salts, 431.
Cyanobenzoic acid, parabromometa-, 337.
Cyanobenzoylacetone, α-, 451.
Cyanocamphor, azo-derivatives of, 1343.
Cyanocarbamides, 702.
Cyanocinnamic acid, α-, 1087.
Cyanogen flame, experiments on, TRANS., 215.
Cyanomethæmoglobin, 361.
Cyanonitrometaxylene, 1437.
Cyanoparatolylformamidine, 707.
Cyanophenylformamidine, 707.
Cyanothiocarbamides, 702.
Cymene, oxidation of, 724.
—— synthesis of, 1310.
Cysteïn, 1111.
Cystin, 1111.
—— presence of, in the horse's liver, 526.

D.

Darapskite, 124.
Datura stramonium, alkaloïds of, 232.
Daturic acid, bromo-, 582.
—— —— salts of, 582.
Daturone, 582.
Decacetyldiglucoheptose, 1167.
Decamethylenediamine, 1181.
Decamethyleneimine, 1181.
Decyl acetate, bromo-, 691.
—— benzoate, chloro-, 691.
Decylacetylene, 1164.
Decylene and its derivatives, 691.
—— glycol, 691.
Dehydracetic acid, 584.
—— —— bromo-, 584.
—— —— constitution of, 587.
—— —— oxy-, 585.
—— —— preparation of, 296.
—— chloride, 587.
Dehydracetylpæonol, 846.
Dehydrocholic acid, 741.
—— —— chloro-, 741.
Dehydrocinchen dibromide, 1012.
Dehydrocinchonine dibromide, 1011.
Dehydrodiacetovanillone, 61.
Dehydrodiacetyllevulinic acid, action of ammonia on, 1429.
—— —— action of benzaldehyde on, 1429.
—— —— action of hydroxylamine and phenylhydrazine on, 1429.
—— hydrazone, 1429.
—— oxime, 1429.
Dehydrodiacetylpæonol, 845, 846.
Dehydrodiacetylresacetophenone, 846.
Dehydrodypnopinacolin, 995.
Dehydromethylacetylpæonol and its derivatives, 846.
Dehydronicotine, 1010.
—— dibromo-, 1497.
Dehydrothiotoluidine, synthesis of, 839.
Density, maximum, of water, 7.
—— molecular weight, diathermanous power, and refractive index of a substance, relation between, 1.
—— of liquefied gases and of their saturated vapours, determination of, 934, 1043.
Deoxybenzoïn, action of paramidodimethylaniline on, 855.
—— chloro- and diiodo-, 451.
—— derivatives of, 1227.
—— parachloro-, 1227.
—— paranitro-, 1227.
—— preparation of, 1095.
—— sodium derivative of, 171.
Deoxybenzoïns, 338.
Deoxyfulminuric acid, 1417.
Deoxystrychnic acid, 1014.
Deoxystrychnine, 1013.
Desaurin, 1095.
—— action of sulphuric acid and of aniline on, 1096.
—— parachloro-, 1227.
Desaurins, new method of formation of, 340.
Desiccator, new form of, 524.
Desmine- and heulandite-groups, relations between minerals of the, 417.
Desylacetic acid, 1002.
Dextran, thermochemistry of, 764.
Dextrin, action of alkaline mercuric cyanide on, 1032.
—— estimation of, in beer and beer wort, 248.
—— preparation of, 577.
Dextrins, fermentability of, 922.
Dextrose, action of alkaline mercuric cyanide on, 1032.
—— cane-sugar, and invert-sugar, examination of mixtures of, 248.
—— disappearance of the multirotation of, in ammoniacal solution, 1419.
—— estimation of, in beer and beer wort, 248.
—— estimation of, in vegetable products, 249.

Dextrose, fermentation of, with *Bacillus ethaceticus*, TRANS., 436.
—— from sulphite cellulose and from fir wood, 801.
—— obtained from cane sugar by means of invertase, specific rotatory power and cupric-reducing power of, TRANS., 408.
Dextrose. See also Glucose.
Dextrose-series, ascent of the, 1164.
Dextroso-cellulose, 907.
Diabase, products of the weathering of, 1412.
Diabetes, artificial production of, 364.
—— variations of glycolytic and saccharific powers of blood in, 517.
Diabetic, behaviour of milk sugar in a, 903.
Diacetallylthiocarbamide, 1327.
Diacetin, preparation of, 289.
Diacetodiketohexamethylenedicarboxylic acid, 586.
Diacetohydroxamic acid, 699.
Diacetonamine platinothiocyanate, 287.
Diacetophenonethylenediphenyldiamine, 633.
Diacetoxydiphenyl sulphoxide, 1077.
Diacetyl, preparation of, 425.
Diacetylacetone, TRANS., 825, 858.
—— chlorinated, 811.
—— refractive and dispersive powers of, TRANS., 860.
Diacetylamidoethenylamidocarvacrol, 309.
Diacetyl-1 : 4-amidonaphthol, 862.
Diacetylchloralammonia, trimolecular, 134.
Diacetyldiamidotoluene, dinitro-, 1197.
Diacetyldiamylquinol, 1444.
Diacetyldiisoeugenol, 46.
Diacetylglycerol, 288.
—— chloro-, 289.
Diacetylindigotin, 480.
Diacetylisoeuxanthone, 504.
Diacetylmetachlorobromoquinol, TRANS., 563.
Diacetylmetadichlorobromoquinone, TRANS., 567.
Diacetylmetadichlorodibromoquinol, TRANS., 580.
Diacetylmetadichloroquinone, TRANS., 560.
Diacetylmetapropenylcatechol, 973.
Diacetylmethylenediamine, 579.
Diacetylnitro-xylidine, 1437.
Diacetylorthodiamidotoluene, nitro-, 1197.
Diacetylorthodiamines, 1197.
Diacetylparadichlorobromoquinol, TRANS., 565.
Diacetylpiperazine, 211.
Diacetyl-β-resorcylonitrile, 317.
Diacetylrubbadin, 1076.
Diacetyltartaric acid, stereochemistry of, 669, 758, 759.
Diacetyltartaric-derivatives, rotatory power of, 669.
Diacetyltrichlorobromoquinol, TRANS., 593.
Diallylacetone, 435.
Diallylacetonedicarboxylic acid, 435.
Diallyldithiotetrahydrotriazole, 292.
Diaminechromium hydrogen thiocyanate, compounds of nitrogenous bases with, 1000.
Diamines in diseases, 518.
—— ortho-, 1472.
—— —— action of formaldehyde on, 1496.
—— —— and α-hydroxy acids, constitution of the compounds obtained from, 1359.
Diammonium imidosulphonate, TRANS., 946.
Diamond, artificial corrosion of, 1394.
—— specific heat of, 761.
Diamonds, discovery of, in meteoric iron, 284.
Diamylamine, chloro-, action of sodium and potassium cyanide on, 804.
Diamylcatechol, 1445.
Diamylcyanamide, 804.
Diamylpyrogallol, 1445.
Diamylquinol, 1443.
—— phenylcarbamate, 1444.
Diamylquinone, 1444.
Diamylresorcinol, 1444.
Dianildicyandiamide, 1323.
Dianilidobenzene, para-, derivatives of, 1450.
Dianilidodimetanitrobenzophenone, para-, 336.
Dianilidosuccininanilide, acetyl derivatives of, 55.
Dianisylditrosacyl, 971.
Diapocinchonine, 1253.
Diargentic sodium imidosulphonate, TRANS., 975.
Diarrhœa, sulphates and ethereal hydrogen sulphates in urine during, 1505.
Diastase, 92.
Diastatic action, TRANS., 689.
Diathermanous power, refractive index, density, and molecular weight of a substance, relation between, 1.
Diazinedicarboxylic acid, 507.
Diazoamidobenzene, action of paratoluidine on, 978.
—— meta- and para-dichloro-, action of paratoluidine on, 978.
Diazoamido-compounds, 977.
—— —— action of acetic anhydride on, 458.

Diazoamido-compounds, action of aniline hydrochloride on, 979.
—— —— conversion of, into azoamido-compounds, 977.
—— —— ethylene derivatives of, Proc., 1892, 119.
Diazoamido-ψ-cumene, action of paratoluidine on, 978.
Diazoamido-ψ-cumeneparatoluene, 979.
Diazoamidometachlorobenzeneparatoluene, 979.
Diazoamidoparachlorobenzeneparatoluene, 979.
Diazoamidotoluene, ortho-, 459.
Diazobenzaldehyde, ortho-, 1106.
Diazobenzene, action of, on acetonedicarboxylic acid, 161.
—— chloride, action of benzaldoxime on, 163.
—— —— action of hydroxylamine on, 710.
—— perbromide, 316.
Diazobenzenamidocarbazole, 617.
Diazobenzeneglyoxaline, 1493.
Diazobenzene-β-naphthylamine, action of dimethylaniline on, 980.
Diazobenzenepiperazine, 211.
Diazo-compounds, action of oximes on, 163, 1079.
—— —— new synthesis by means of, 1198.
—— —— velocity of decomposition of, by water, 768.
Diazodibenzylamine, ortho-, 890.
Diazoguanidine salts, 1298.
Diazohippurylamide, 113.
Diazonaphthalene salts, nitro-, decomposition of, with alcohol, 622.
Diazonaphtholsulphonic acid, 721.
Diazonaphthylenesulphonic acid [1 : 2], 345.
Diazotoluene chloride, para-, action of hydroxylamine on, 710.
Dibenzamide, imido-, 713.
Dibenzenesulphonediphenetidine, 65.
Dibenzenesulphoneorthotoluylenediamine, 66.
Dibenzenesulphoneparaphenylenediamine, 65.
Dibenzenylazosulphime, 1109.
Dibenzimidine, 1110.
Dibenzoyldihydroxyanhydroecgonine, derivatives of, 1016.
Dibenzoyldiisoeugenol, 46.
Dibenzoyldiorthohydroxystilbene, 168.
Dibenzoylorthohomosalicenylamidoxime, 320.
Dibenzoylparahomosalicenylamidoxime, 319.
Dibenzoylpyridine, 1365.
Dibenzoylstilbene, action of phenylhydrazine on, 995.
Dibenzyl ketone, 851.
Dibenzylacetoacetic acid, 963.
Dibenzylamidosulphonic acid, 476.
Dibenzylamine nitrate, 476.
—— paradinitrorthodichloro-, 445.
Dibenzylaniline, paradinitrorthodichloro-, 445.
Dibenzylcarbamic chloride, 1083.
Dibenzylcarbinamine, 1093.
—— dibenzylcarbinaminethiocarbamate, 1094.
Dibenzylcarbinol, 851, 1094.
Dibenzylcyanocarbamide argentocyanide, 1084.
Dibenzyldiphenylsuccinonitrile, symmetrical, 619.
Dibenzylditolylcarbamide, 1083.
Dibenzylene dicyanide, 619.
Dibenzylidene-2 : 6-lutidine, 1361.
Dibenzylidenenitrotolidine, 852.
Dibenzylideneparadiamidodiphenylmethane, 618.
Dibenzylorthodiamidotoluene, nitro-, 1197.
Dibenzylparatolylcarbamide, 1083.
Dibenzylphenylhydrazine, diorthonitro-, 1456.
Dibenzylpimelic acid, ωω′-, dissociation constant of, Trans., 702.
Dibenzylpyridine, 1364.
Dibenzylsulphonemethane, 612.
Dibenzylsulphonephenylmethane, 623.
Dibenzylsulphonethiobenzylmethane, 612.
Dibornylamine, 1238.
Dibornylthiocarbamide, 1238.
Dicalcium phosphate, crystallisation of, 407.
—— —— solubility of, in solutions of phosphoric acid, 684.
Dicampholylcarbamide, 1345.
Dicarboxyglutaconic acid, Trans., 791.
Dichlorhydrin metahydroxybenzoate, an isomeric, 471.
Dicresol, 1467.
—— nitro-, 852.
Dicresoldisulphonic acid, 1467.
Dicyanacetylethylenediamine, 1071.
Dicyanacetylpentamethylenediamine, 1071.
Dicyanonaphthalene [1 : 2], 1477.
Dicyanophenylhydrazine, action of ethyl acetoacetate on, 597.
—— condensation of, with fatty aldehydes, 596.
Dicyanostilbene, 618.
Didymium spectra, 686.
Dielectric power and electrolytic conductivity, coexistence of, 759.
Diethoxydiamidodiphenylamine, 314.
Diethoxydimethyldiamidophenazine, 315.

Diethoxydiphenylcarbamide, 833.
Diethoxydiphenylenedinitrosacyl, para-, 972.
Diethoxysulphophenylhydrazide, para-, 1082.
Diethyl camphorate, 500, 1102.
—— dichlorobenzoparadifurfuran-α-dimethyl-β-dicarboxylate, para-, 609.
—— diphenylazimethylenedicarboxylate, 453.
—— furfuryllutidinedicarboxylate and its salts, 1362.
—— hydrofurfuryllutidinedicarboxylate, 1362.
—— isocamphorate, 501.
—— malonate, action of methylene iodide on, 1304.
—— quinoneparadifurfuran-α-dimethyl-β-dicarboxylate hydrochloride, 610.
—— sulphoxide, diamido-, picrate of, 130.
Diethylamidocaproic acid, 294.
Diethylamidophenylarsine oxide, 1321.
Diethylamine platinothiocyanate, 286.
Diethylaniline, action of silicon tetrachloride on, TRANS., 457.
Diethylcamphor, 200.
Diethyldiamidoquinoxazone, 888.
Diethyldithiophosphinic acid, 1422.
Diethylethoxydiphenylsulphonephenylenediamine, 161.
Diethylidenecinchonine, 1252.
Diethylidenecinchoxine, 1252.
Diethylorthotoluidine, paramido-, 1078.
Diethylpentanetetracarboxylic acid, dissociation constant of, TRANS., 704.
Diethylphenylformamidine, 707.
Diethylpimelic acid, ωω′-, dissociation constant of, TRANS., 701.
Diethylpiperazine, 212.
Diethylpiperidine, 1358.
Diethylpropargylamine hydriodide, 30.
Diethylquinol, trinitro-, action of dimethylmetadiamidobenzene and of α-naphthylamine on, 315.
—— —— action of dimethylparamidobenzene on, 315.
—— —— action of paradiamidobenzene on, 314.
Diethylsulphonephenylsulphonemethane, and its chloro- and bromo-derivatives, 613.
Diethylsulphonephenylsulphonemethylmethane, 613.
Diethylsulphonethiophenylmethylmethane, 613.
Diethylthiocarbamide, unsymmetrical, 216.
Diethyltoluylenediamine, 66.
Difenchyloxamide, 1239.
Difenchylthiocarbamide, 1239.
Diffusion and electrolysis, theory of, 935.
—— of aqueous solutions, 1265.
Diformylparadianilidobenzene, 1451.
Difurfurylcarbamide, 43.
Difurfurylthiocarbamide, 43.
Difurylhydroxycyanidine, 1008.
Difurylmethylcyanidine, 1006.
Difurylnaphthoquinoxaline, 1475.
Difurylquinoxaline, 1475.
Difuryltoluquinoxaline, 1475.
Digestibility of raw and boiled meat, 1367.
Digestion and absorption of fat oils by plants, 1118.
—— gastric, influence of amido-acids on, 742.
—— of carbohydates, 742.
—— of pentose carbohydrates, 645.
—— of starch by dogs, 516.
—— peptic, influence of wine on, 87.
Digestive ferments in crustacean eggs, 362.
—— tract of certain animals, search for a cellulose-dissolving enzyme in, TRANS., 352.
Digitaleïne, 222.
Digitaligenin, 1482.
Digitalin, 1482.
Digitalonic acid, 1241.
—— lactone, 1242, 1482.
Digitalose, 1482.
Digitogenin, preparation of, 1483.
Digitonin, 501.
Dihydrazidopimelic anhydride, 435.
Dihydrazineditolyldisulphonic acid, 1467.
Dihydriodoapoquinidine, 640.
Dihydriodocinchonine, 514, 639.
Dihydriodoquinidine, 640.
Dihydroarecaïdine, 739.
Didydroarecoline, 739.
Dihydrobenzene, synthesis of, 1074.
Dihydrobenzyldimethylamine, $\Delta^{3:5}$-, 358.
Dihydrocarveol, 499.
Dihydrocarvylamine, 499.
Dihydrodimethylnaphthylpropionic acid, 871.
Dihydroisosantinic acid, 871.
Dihydro-α-naphthoic acid, labile Δ^{2}-, 192.
—— —— stable Δ^{1}-, 192.
Dihydro-β-naphthoic acid, labile Δ^{3}-, 193.
—— —— stable Δ^{2}-, 193.
Dihydroparaxylene, synthesis of, 1182.
Dihydrophenanthridine, 197.
Dihydrophthalic acid, $\Delta^{1:4}$-, 1216.
—— —— $\Delta^{4:6}$-, 1215.
—— —— cis-$\Delta^{3:5}$-, 1215.
—— —— trans-$\Delta^{3:5}$-, 1214.

Dihydroquinazoline, 219.
Dihydrosantinic acid, 871.
Dihydroterephthalic acid, nitrile of, 834.
Dihydrotrimethylindole methiodide, 614.
Dihydroximidopropionic acid, primary, 815.
—— —— secondary, 816.
Dihydroxyacridine, 1108.
Dihydroxyaldehydes, aromatic, nitrogenous derivatives of, 317.
Dihydroxyamylpiperidine aurochloride, 86.
Dihydroxyanhydroecgonine, 1015.
Dihydroxyanisoïl, dinitro-, 596.
Dihydroxyaurindicarboxylic acid, 1469.
Dihydroxybenzoic acid, 1 : 3 : 5-, action of chlorine on, 1461.
—— —— dichloro-, 1461.
—— —— trichloro-, 1461.
Dihydroxybutyric acid, 957.
Dihydroxycaproic acid, salts of, 959.
Dihydroxy-compounds, aromatic ortho-, reagent for, 1133.
Dihydroxydiketotetrahydronaphthalene, 859.
Dihydroxydinitrodiphenylamine, 310.
Dihydroxydiphenyl sulphoxide, 1077.
Dihydroxydiphenyldibenzylmethane, 851.
Dihydroxyfluoran, 970.
Dihydroxyhexamethylene, cistranspara-, 833.
Dihydroxyhydrobenzoïn, ortho-, 168.
—— —— diesoanhydride, 168.
Dihydroxyhydrolapachol, Trans., 647.
Dihydroxy-α-naphthaldehyde, β-ortho-1459.
Dihydroxynaphthaquinone, 720.
Dihydroxy-β-naphthaquinone, 494.
Dihydroxynaphtho-xanthones, 1100.
Dihydroxyorthocarboxyphenylpropionic acid, lactone of, 720.
Dihydroxyperchloromethylcyanidine, 1291.
Dihydroxy-α-picoline, α′γ-, Trans., 723.
—— dibromide, Trans., 724.
Dihydroxystilbene, ortho-, 168.
Dihydroxytartaric acid, behaviour of, with sodium hydrogen sulphite, 148.
Dihydroxythiobenzenes, 1316.
Dihydroxythymoquinone, 1098.
Dihydroxytoluene, synthesis of the sixth, 447.
Dihydroxytriphenylmethane, meta-, paranitro-, 621.
—— para-, metanitro-, 620.
—— —— orthonitro-, 621.
—— —— paranitro-, 621.
Dihydroxytriphenylmethanedicarboxylic acid, ortho-, para-, and meta-nitro-, 621.
Dihydroxyvaleric acid, salts of, 959.
Dihydroxyxanthone, bromo-derivatives of, 1226.
Diimide, attempts to prepare, 1430.
Diisoamylselenocarbamide, 216.
Diisoamylthiocarbamide, unsymmetrical, 216.
Diisobutylallylamine, 31.
Diisobutylamine, chloro-, 1173.
Diisobutylcyanamide, 1173.
Diisoeugenol and its derivatives, 45.
Diisopropylpimelic acid, ωω′-, dissociation constant of, Trans., 702.
Diketohexene, meta-, hexachloro-, 1461.
—— para-, hexachloro-, 447.
—— —— pentachloramido-, 450.
Diketohydronaphthalene hydrate, dichloronitro-αβ-, 1232.
—— tetrachlorortho-, its hydrates and alcoholates, 858.
Diketo-γ$_1$-methyljulole, α$_1$α$_2$-, 496.
Diketones, action of bleaching powder and of hypochlorous acid on, 720.
—— fatty 1 : 2-, preparation of, 425.
Diketopentamethylenehydroxycarboxylic acid, tetrachloro-, 836.
—— —— trichloro-, 835.
Dimethoxystilbene, ortho-, 719.
—— para-, 719.
Dimethyl camphorate, 1102; Trans., 1092.
Dimethylacetobutylamine, 1244.
Dimethyladipic acids, stereoisomeric, 430.
Dimethylalloxanhydrazone, 442.
Dimethylamidoazobenzene, parabromo-, 980.
Dimethylamidocrotonanilide, β-, 708.
Dimethylamidophenylarsine oxide, 1321.
—— sulphide, 1321.
Dimethylamidopropionic acid, 1302.
Dimethylamidoquinoxazone, 888.
Dimethylamine hydrogen diaminechromium thiocyanate, 1000.
—— platinothiocyanate, 286.
Dimethylaniline, action of, on ketones, 855.
—— refractive power of, at different temperatures, Trans., 302.
Dimethylapionylcarboxylic acid, 1315.
Dimethylbenzimidazole [2 : 2′-], 632.
Dimethylcinchonine, 892.
Dimethylcyanidine, amido-, 1291.
Dimethyldiamidodiphenyltolylmethane, paranitro-, 189.
Dimethyldiamidoquinoxazone, 888.
Dimethyldiazine, 507, 633.
Dimethyldihydropentene methyl ketone, Trans., 77.
—— —— ketoxime, Trans., 79.
Dimethyldihydropentenedicarboxylic acid, Trans., 81.

Dimethyldihydroquinazoline, $\beta\gamma$-, 218.
Dimethyldihydroxyglutaric acid, 437.
—— —— dilactone of, 437.
—— —— lactone of, 436.
—— acids, stereoisomerism of, 436.
Dimethyldiketohexamethylene, 1183.
Dimethdiphenylsuccinonitrile, symmetrical, 619.
Dimethyldipiperidyl, 1487.
Dimethyldipyridyl, $\beta\beta$-, 629.
Dimethyldiquinoyline, 1107.
Dimethyldisalicylaldehyde, para-, 1459.
Dimethyldithiotetrahydrotriazole, 293.
Dimethylethylnaphthalene, 872.
Dimethylethylsulphine, preparation of, 1422.
Dimethylethylthymoquinol, 1312.
Dimethylfraxetin, 628.
Dimethylglyceric acid, $\alpha\beta$-, from angelic acid, 297.
Dimethylheptylethylene, α-, 133.
Dimethylhexylcarbinol, 133.
Dimethylhydroxybutyrolactonecarboxylic acid, 436.
Dimethylhydroxyquinoline, 78.
Dimethylisoxazole, $\alpha\gamma$-, reduction of, 507.
Dimethylmetamidophenol, nitroso-, 887.
Dimethyl-α-methoxy-μ-thiomethylimidazole, $\nu\beta$-, 153.
Dimethylmethylenehydrazine, 457.
Dimethylmethyleneimidosulphonic acid, 701.
Dimethylnaphthalloxazine, 70.
Dimethylnaphthylpropionic acid, 871.
Dimethylorthanisidine, action of nitric acid on, 159.
Dimethylparethoxyphenylpyrazolone, 1080.
Dimethylpentamethylenemethylcarbinol, TRANS., 79.
Dimethylpentanetetracarboxylic acid, dissociation constant of, TRANS., 704.
Dimethylphenylcyanidine, 1110.
Dimethylphthalic acid, para-, 872.
Dimethylpimelic acid, $\omega\omega'$-, dissociation constant of, TRANS., 701.
—— acids, stereoisomeric, 430.
Dimethylpiperazine, 212.
Dimethylquinoline, $\alpha\beta$-, 1107.
—— amido-, 729.
—— nitro-, 729.
Dimethylquinolone, 4-nitro-, 880.
Dimethylquinitol, 1183.
Dimethylracemic acid, 698.
Dimethylrubbadin, 1077.
Dimethyltetrahydroquinoline, 614.
Dimethyl-Δ^2-tetrahydropyridine, 1 : 2-, 1243.
Dimethylthetincarboxylic acid, 1433.
Dimethylthetindicarboxylic acid, 1433.
Dimethylthiocarbamide, unsymmetrical, 216.
Dimethylthiohydantoïn, 151.
Dimethyltoluidine, ortho-, action of formaldehyde on, 1320.
Dimethyltriamidodiphenylamine, 1109.
Dimethyltriamidodiphenyltolylmethane, 189.
Dimethyltrihydroxybenzophenone, 1225.
Dimethyltrimethylenedisulphone sulphide, 593.
Dimethyltrimethylenetrisulphone, 591, 593.
Dimethylumbelliferonecarboxylic acid, $\alpha\beta$-, 432.
Dimethylxanthone, 1093.
Dinaphthenylimidine, β-, 1110.
Dinaphtho-xanthone, 1099.
Dinaphthylamidinecarbamide, 1008.
Di-β-naphthylcarbamic chloride, thio-, 165.
Dinaphthylcarbamide, tetranitro-α-, 467.
—— tetranitro-β-, 467.
Di-β-naphthylcarbamide, unsymmetrical, thio-, 165.
Dinaphthyl-$\alpha\gamma$-diketopiperazine, β-, 1342.
Dinaphthyl-$\alpha\gamma$-dimethyl-$\beta\delta$-diketopiperazine, β-, 1337.
Di-α-naphthylformamidine, 706.
Dinaphthylmethylcyanidine, 1110.
Di-β-naphthylphenylcarbamide, thio-, 166.
Dinaphthylthiocarbazide, ρ-, 513.
Dinaphthylthiocarbazone, β-, 513.
Dinitrosacyls, 971.
Dioxydehydronicotine, dibromo-, 1497.
Dioxymethylenephenyloximidoacetic acid, 327.
Dioxythiophenetoïl, 1316.
Dipentene, dihydrochloro-, action of chlorine on, 1350.
Dipentenenitrolanilide, α-nitroso-, 1348.
Dipentenenitrolbenzylamine, hydrochloro-, 1349.
Diphenyl, dimetanitrodiorthamido-, 481.
Diphenylacetonitrile, 344, 1094.
Diphenylamine, action of silicon tetrachloride on, TRANS., 454.
—— diamido-, 1109.
—— formation of, from orthobromobenzoic acid, 1188.
Diphenylamineorthoparadisulphonic acid, 333.
Diphenylanthracene dibromide, 720.
—— dihydride, 720.
Diphenylcarbamide, bromo-, 833.
—— metachloro- and parachloro-, 979.
—— unsymmetrical thio-, 164.
Diphenylcrotolactone, 1002.
Diphenylcyanamide, PROC., 1892, 96.

Diphenyl-derivatives, dehydration of amides in contact with, 617.
Diphenyldiamidodicarboxylic acid, 1464.
Diphenyldi-β-naphthylcarbamide, symmetrical, 166.
—— thio-, 165.
—— unsymmetrical, 167.
Diphenylene oxide, synthesis of, 1470.
Diphenyleneazone, 184, 482.
—— diamido-, 184.
—— dioxide, 183.
—— oxide, 183.
Diphenylenediamine, para-, 481.
Diphenylenehydrazone, 184.
Diphenylformamidine, metadinitro-, 706.
—— metanitro-, 707.
Diphenylfurfurylguanidine, 43.
Diphenylhydantoïn, 1334.
Diphenylhydrazoneopianic acid, 1210.
Diphenylmaleïc acid, action of soda on, 297.
—— anhydride, 178.
Diphenylmethane, paradiamido-, 618.
—— —— nitro-derivatives of, 618.
Diphenylmethyleneaniline, 1195.
Diphenylmethylethophenazonium hydroxide, 1108.
Diphenylnitrosamine, orthonitro-, 332.
Diphenylorthamide, preparation of, 1198.
Diphenylpropionic acid, 849.
—— —— preparation of, 1228.
Diphenylpyrrolidone, 1003.
Diphenylpyrrolone, 1003.
Diphenylquinol, nitro-derivatives of, 310.
Diphenylresorcinol, tetra-, penta-, and hexa-nitro-, 310.
Diphenylsuccinonitriles, α- and β-, 619, 620.
—— stereoisomeric, 619.
Diphenyltetraketone, 69.
Diphenylthiazolecarboxylthiamide, 638.
Diphenylthiocarbamide, 600.
Diphenylthiohydantoïn, 468.
Diphenylthiourea, unsymmetrical, Proc., **1892**, 96.
Diphthalimidoethyl sulphide, 130.
—— sulphoxide, 130.
Diphthalimidoethylsulphone, 131.
Diphtheria, chemical pathology of, 744.
Dipiperazine, paradinitro-, 210.
Dipiperidyl, 2 : 3-, 1365.
Dipotassium imidosulphonate, Trans., 952.
Dipropargyl and benzene, 1436.
—— constitution of, 1437.
—— molecular refraction of, 1437.
Dipropylcarbamide, unsymmetrical, 1421.
Dipropylpimelic acid, ωω′-, dissociation constant of, Trans., 701.
Dipropyltrimethylenetrisulphone, 592.
Dipseudocumylcarbamide, 832.
Dipyridyl carbonyl bromoplatinosite, 353.
—— —— chloroplatinosite, 352.
Dipyridyl-aa-dicarboxylic acid, 75.
Disanhydrotetrabenzamidotetrahydroxyoctene, 1002.
Disazobenzene, chloronitro- and chloronitronitroso-derivatives of, 456.
—— nitronitroso-derivatives of, 455.
Disazobenzenephenylhydrazine, pentanitro-, 456.
Disbenzeneazoacetine, 161.
Diseases, diamines in, 518.
—— infectious, ptomaïnes of, 1258.
Disodium imidosulphonate, Trans., 954.
Dispersion and refraction of sodium chlorate, 1.
Dissociation constants of organic acids, Trans., 696.
—— —— of stereoisomeric nitrogen compounds, 1268.
—— electrolytic, and absorbent power of coloured salts, 757.
—— —— and osmotic pressure, theories of, 1143.
—— —— of salts, determination of, by means of solubility experiments, 1143.
—— hypothesis and strong solutions, 108.
—— in dilute solutions of tartrates, 588, 1144.
—— of bismuth chloride by water, effect of sodium chloride on the, 122.
—— of electrolytes, correction in the calculation of the heat of, 931.
—— of liquid nitrogen peroxide, Trans., 242.
—— of phosphonium bromide, 401.
Dissolution, abnormal, 1047.
—— behaviour of molecular compounds on, 1154.
—— change of volume on, 264.
Dissymmetry, molecular, 399.
Disuccinimidodihydroxamic acid, 138.
Disulphanilic acid, 333.
Disulphones, formation of trisulphones from, 613, 850.
Ditetramethylene diphenyl glycol, Trans., 66.
Dithiocarbamates, aromatic, 55.
Dithiocarbonic acids, 306.
Ditolenylimidine, 1110.
Ditoluamide, para- and ortho-, 712.
Ditolyl ketone, diamido-, 1460.
—— —— dinitro-, 1460.
—— meta-, 851, 852.

Ditolyl dicyanide, meta-, 852.
Ditolylamine, orthamido-, derivatives of, 853.
—— orthamido-, formation of an, from parahydrazotoluene, 853.
Ditolylbenzylcarbamide, para-, 1083.
Ditolylcarbamic chloride, para-, 1083.
Ditolylcarbamide, meta-, 832.
Ditolylcarbazide, para-, 512.
Ditolylcyanocarbamide, diargentocyanide, para-, 1084.
Ditolyldicarboxylic acid, 852.
Ditolyl-αγ-diethyl-βδ-diketopiperazines, para-, 1338.
Ditolyl-αγ-diketopiperazine, ortho-, 1334.
—— para-, 1337.
Ditolyl-αδ-diketopiperazine, para-, 1336.
Ditolyldisulphonic acid, 1466.
—— —— amido-, 1467.
Ditolylhydantoïn, ortho-, 1334.
—— para-, 1336.
Ditolylhydroxycyanidine, 1008.
Ditolylmethylcyanidine, 1110.
Ditolylsemithiocarbazide, ortho-, TRANS., 1017.
—— para-, TRANS., 1018.
Ditolylthiocarbazide, ortho-, 513.
—— para-, 512.
Ditolylthiocarbazone, ortho-, 513.
—— para-, 512.
Divalolactone, 814.
Dixanthone, 1097.
Dixylylcarbamide, 832.
Dogs, digestion of starch by, 516.
Dopplerite, 689.
Double salts, solubility of, 1145.
Dulcitol, a pure fermentation of, TRANS., 254.
—— and calcium chloride, compound of, TRANS., 275.
—— and its derivatives, optical properties of, 1419.
—— thermochemistry of, 764.
Duodecylacetylene, 1164.
Durene, chloro-, action of sulphuric acid on, 968.
—— iodo-, 967.
—— mono- and di-chloro-, 967.
Durenesulphonic acid, chloro-, 1465.
Dyeing with aniline black in the dry way, 323.
Dyes of the triphenylmethane group, 187.
Dypnopinacolene, 994.
Dypnopinacolin, α-, 993.
—— alcohol, 994.
Dypnopinacolin, β-, 994.
Dypnopinacone, 993.

E.

Earth-nut cake and meal, approximate estimation of adulteration of, 1535.
—— meal, 92.
Earths of the cerium and yttrium 1400.
Ecgonine, constitution of, 360.
Effusion of gases, lecture experiment on, 1150.
Egg yolk, estimation of fat in, 1134.
Eggs, crustacean, digestive ferment in, 364.
Elaïdic and oleïc acids, stereoisomerism of, 812.
Ellagic acid, 990.
Elaterite, 689.
Electrical behaviour of metals in salt solutions, 393.
—— conductivities, study of the chemical constitution of neutralisation of acids and bases by means of their, 2.
—— conductivity of a solution, alteration of, by addition of a non-electrolyte, 1382.
—— —— of lead dioxide, 672.

—— laws of, 1037.
—— of potassium acetate solutions, TRANS., 10.
Electrolytes, changes of E.M.F. volume and temperature on mixing, 930.
—— correction in the calculation of the heat of dissociation of, 931.
—— separation of precipitates at the boundary of, 1038.
—— thermoelectric phenomena at the contact of two, 1037.
Electrolytic conductivity and dielectric power, coexistence of, 759.
—— —— of polybasic acids, 1145.
—— dissociation and absorbent power of coloured salts, 757.
—— —— and osmotic pressure, theories of, 1143.
—— —— of salts, determination of, by

means of solubility experiments, 1143.
Electrolytic gas, ignition temperature of, 680.
—— preparation of metallic alloys, 394.
—— separation of metals, new principle of, 1521.
Electromotive activity of the ions, 671.
—— force of gas batteries, 393.
—— —— relation of latent heat, specific gravity, &c., to, 257.
—— —— volume, and temperature, changes of, on mixing electrolytes, 930.
—— forces, new method of measuring, 105.
—— —— of metallic salts, 255.
Electrostenolysis, 393.
Element, new, in an Egyptian mineral, Trans., 491.
Elements, place of fluorine in the classification of, 11.
—— tabular expression of the periodic relation of, 562.
Endocarditis, infective, chemical pathology of, 744.
Energetics, studies on, 1149.
Energy as the unit of an absolute system of measurement, 1149.
Enzyme, cellulose-dissolving, search for, in the digestive tract of certain animals, Trans., 352.
Ephedra monostachia, ephedrine from, 893.
Ephedrine from *Ephedra monostachia*, 893.
Epichloramine, 29.
Epidibromhydrin, 420.
Equilibrium, chemical, in solutions, 1146.
—— labile conditions of, in mixtures of two substances at a temperature below the melting point of either, 936.
—— of chemical systems under unequal pressures, 937, 1148.
—— of double salts of lead and potassium iodides with their aqueous solutions, 560.
Erucic acid and brassidic acid, stereometric relations of, 429, 812, 1427.
—— —— bromo- and chloro-, 429.
—— —— dichloride, 429.
—— phenylhydrazide, 1428.
Errum hirsutum and *E. Lens*, composition of, 522.
Erythræa centaurium, constituents of, 1261.
Erythritol, thermochemistry of, 764.
Erythrocentaurin, 1262.
Essence of sandal wood, adulteration of, 1379.
Essences, detection of turpentine and other impurities in, 386.
Ethane, absorption-coefficient of, in water, 1044.
—— action of heat on, Trans., 329.
Ethanetetracarboxylic acid, symmetrical, 824.
Ethenyldiamidonaphthyl ethyl ether, 1098.
Ethenyldiamidotoluene and its derivatives, 837.
Ethenyldinitrotoluyleneamidine, 1197.
Ethenylnitrotoluyleneamidine, 1197.
Ethenylorthohomoparahydroxybenzenylazoxime, 321.
Ethenylparahomosalicenylazoximes, 319.
Ethenylpiperonylazoxime, 318.
Ethenyl-β-trichloro-α-hydroxypropenylazoxime, 321.
Ether, influence of, on the velocity of the hydrolytic action of yeast, Trans., 935.
—— solutions, dilute, cryoscopy of, 1045.
Ethereal oils, oxygen compounds of, 868.
Ethereal oils. See Oils.
Ethereal salts, action of sodium on, Proc., **1891**, 167.
—— —— condensation of cyanides with, 431.
—— —— in spirits, estimation of, 387.
Ethoxalylacetylfurfuramidine, 1007.
Ethoxalylacetyltolenylamidine, 1008.
Ethoxyacetamidoquinoline [1 : 4], 1104.
Ethoxyacetophenone, ortho-, 989.
Ethoxyamidoquinoline [1 : 4], 1105.
Ethoxyantipyrine, para-, 1080.
—— salicylate, 1082.
Ethoxyazobenzene, para-, preparation and nature of, 839.
—— reduction of, 839.
Ethoxybenzaldoxime, ortho-, 58.
Ethoxybenzonitrile, ortho-, 58.
Ethoxybenzylamine, ortho-, 58.
Ethoxy-α-bromocinnamene, ortho-, 989.
Ethoxybutyric acid, γ-, 813.
Ethoxycinnoline, 1494.
Ethoxycresol, 447.
Ethoxydiacetylorthophenylenediamine, meta-, 161.
Ethoxydihydroxyquinoxaline, meta-, 160.
—— para-, 734.
Ethoxydiphenylquinoxaline, para-, 732.
Ethoxydiphenylsulphoneorthophenylenediamine, meta-, 161.
Ethoxyhydroxydinitrodiphenylamine, 314.
Ethoxyhydroxymethylquinoxaline, 733.
Ethoxyimidofurfuran, 831.
Ethoxyisosuccinic acid, 1305.
Ethoxymetaxylenesulphonic acid, Proc., **1891**, 190.

Ethoxymethylindole, 955.
Ethoxynaphthazine, 733.
Ethoxyorthophenylenediamine, meta-, 160.
Ethoxyphenanthrazine, para-, 733.
Ethoxyphenyl sulphide, 1316.
Ethoxyphenylacetylene, 989.
Ethoxyphenylchloracrylic acid, ortho-, 989.
Ethoxyphenylhydrazine, para-, and its salts, 1080, 1081.
Ethoxyphenylhydrazinesulphonic acid, para-, 1082.
—— —— —— salts of, 1081.
Ethoxyphenylmethylpyrazolone, para-, 1080.
Ethoxyphenylnaphthostilbazonium chloride, action of ammonia on, 1247.
—— —— action of heat on, 1247.
—— hydroxide, 863.
Ethoxyphenylorthodiamidonaphthalene, 863.
Ethoxyphenylpropiolic acid, ortho-, 989.
Ethoxyphenylsulphonic acids, meta-, ortho-, and para-, and their derivatives, 1089.
Ethoxypiazthiole, para-, 734.
Ethoxypropanilide, α-, 1337.
Ethoxypyridine, α-, 109.
Ethoxyquinoline, derivatives of, 1105.
Ethoxyquinoxaline, para-, 732.
Ethoxyquinoxalinedicarboxylic acid, para-, 733.
Ethoxytetramethylenecarboxylic acid, Trans., 46.
Ethoxytrimethylammonium platinochloride, chlor-, 807.
Ethyl acetates, substituted, hydrolysis of, 1148.
—— acetoacetate, 140, 953.
—— —— —— acetyl and benzoyl, derivatives of, 817.
—— —— action of, on dicyanophenylhydrazine, 597.
—— —— action of phenylhydrazine on, 142, 953.
—— —— action of propylene bromide on the sodium derivative of, Trans., 67.
—— —— aldehydeuramides, 56.
—— —— constitution of, 583, 816, 1072.
—— —— haloïd, derivatives of, 697.
—— —— introduction of acid radicles into, 696.
—— —— magnetic rotation of, Trans., 808, 838.
—— —— stereoisomeric dioximes from, 1175.
—— β-acetoisobutyrate, 74.
Ethyl β-acetoxy-αβ-dibromopropionate, 817.
—— acetonedicarboxylate, 431.
—— —— magnetic rotation of, Trans., 812, 839.
—— acetoneoxalate, refractive and dispersive powers of, Trans., 854.
—— —— magnetic rotation of, Trans., 820, 853.
—— acetophenoneoxalate, magnetic rotation of, Trans., 833, 864.
—— acetosuccinate action of nitrous acid on, 1074.
—— acetothienoneoxalate, 154.
—— —— derivatives of, 303.
—— β-acetoxymethylacrylate, 817.
—— acetylcarbintricarboxylate, 145, 1070.
—— α-acetyl-β′-hydroxyhydromuconate, 143.
—— acetylmethyltrimethylenecarboxylate [1 : 2 : 1], Trans., 67.
—— acetyltartronate, 39.
—— alcohol, heats of combustion and formation of, 1139.
—— —— vapour tension of, 397.
—— allomethyl camphorate, ortho-, 1101.
—— allylacetoacetate, magnetic rotation of, Trans., 809.
—— amidoethylenedicarboxylate, Trans., 792.
—— β-amidocrotonate, magnetic rotation of, Trans., 828, 859.
—— —— refractive and dispersive powers of, Trans., 861.
—— amidomethylthiazolecarboxylate, 697.
—— 2 : 5-amidonitrobenzoate, 326.
—— amidothiazylisobutyrate, 697.
—— amidotolyloxamate, 1208.
—— anilacetoacetate, action of hydrocyanic acid on, 1196.
—— β-anilidoacrylate, 818.
—— 2 : 5-anilidonitrobenzoate, 326.
—— anilidophenylsuccinamate, 820.
—— anilidotrinitrophenylmalonate, 1218.
—— —— nitrite, 1217.
—— anilidotrinitrophenyltartronate, 1218.
—— azimethylenedicarboxylate, 453.
—— benzeneazocamphocarboxylate, 1344.
—— benzenesulphonate, 1220.
—— benzenesulphoneorthamidobenzoate, 334.
—— benzoparadifurfuran-α-dimethyl-β-dicarboxylate, 610.
—— benzoylacetate, action of propylene bromide on the sodium compound of Trans., 82.

Ethyl benzoylacetate, magnetic rotation of, Trans., 831, 861.
—— —— stereoisomeric dioximes from, 1175.
—— benzoylmethyltrimethylenecarboxylate, Trans., 84.
—— α-benzylacetoglutarate, 962.
—— benzyldicarboxyglutaconate, action of phenylhydrazine on, Trans., 795.
—— bromacetoacetate, 143, 818.
—— α-bromethylacetoacetate, 144.
—— bromide, bromination of, 577, 1414.
—— bromobenzenesulphonate (para), 1220.
—— α-bromocinnamates, action of phenylhydrazine on, Trans., 279.
—— bromodinitrophenylmalonate nitrite, 1219.
—— bromomalonate, action of potassium acetate on, 39.
—— α-bromomethylacetoacetate, 144.
—— bromopropyl ether, 420.
—— bromosuccinate, action of α- and β-naphthylamines on, 860.
—— bromotrinitrophenylmalonate, action of nitric acid on, 1217.
—— —— nitrite, 1217.
—— bromotrinitrophenyltartronate, 1218.
—— butyl ether, 28.
—— camphocarboxylate, 348.
—— —— action of sodium benzyloxide on, 74.
—— camphorate, 501.
—— camphorates and isocamphorates, 500.
—— carbacetoacetate, so-called, 819.
—— carbethoxyethylacetoacetate, 1179.
—— carboxyethylacetoacetate, 1070.
—— α-carboxyethylpimelate, 427.
—— chloracetate, action of sodium on, 953.
—— chloracetoacetate, constitution of, 697.
—— chlorobenzenesulphonate (para-), 1220.
—— chlorobromomalonate, 39.
—— chlorocarbonate, 963.
—— cinnamate, refractive power of, at different temperatures, Trans., 304.
—— citraconate, action of ethyl sodiomalonate on, 590.
—— cyanacetate, action of hydroxylamine on, 139.
—— —— action of, on aniline, 1072.
—— —— action of, on organic bases, 1071.
—— —— and benzaldehyde, condensation of, 1086.
—— γ-cyanacetoacetate, 819.
Ethyl cyanide, action of sodium on, 576.
—— α-cyanisopropyl ketoxime, 80.
—— cyanocinnamamate, 1087.
—— α-cyanocinnamate, 1086.
—— α-cyanopropionate, additive compound of hydrogen cyanide with, 1301.
—— cyanopyruvate oxime, 431.
—— cyanotricarballylate, 1181.
—— dehydrocholate, 741.
—— diacetoacetate, magnetic rotation of, Trans., 823, 854.
—— —— refractive and dispersive powers of, Trans., 857.
—— diacetosuccinate, action of nitrous acid on, 1074.
—— diallylacetonedicarboxylate, 434.
—— dibenzoylacetoacetate, 145.
—— dibenzylacetoacetate, 963.
—— dibenzylcarbamate, 1084.
—— dibromosuccinate, action of zinc on, 40.
—— dicarboxyglutaconate, action of ammonia on, Trans., 791.
—— —— action of phenylhydrazine on, Trans., 793.
—— dichloroketohydroxyhydrindenecarboxylate, 858.
—— dichloromalonate, 39.
—— dichloroquinoldiacetoacetate (para-), 609.
—— dichloroquinonediacetoacetate (para-), 609.
—— —— —— additive products of, 610.
—— diethoxyacetoacetate, 955.
—— dihydroxytartrate, 1181.
—— αβ-diisonitrosobutyrate, 1175.
—— dimethyldicyanoadipate, 430.
—— dimethyldicyanopimelate, 430.
—— dimethylsuccinosuccinate, 1182.
—— αβ-dimethylumbelliferonecarboxylate, 432.
—— dinitrophenylacetate, derivatives of, 178.
—— dioxosuccinate, 1181.
—— diphenoxymalonate, 40.
—— ditannacetoacetate, 181.
—— ditolylcarbamate (para-), 1084.
—— ethoxyacetoacetate, 954.
—— ethoxychloracetoacetate, 953.
—— ethoxyhydroxyquinoxalineacetate, 733.
—— ethoxyoxalacetate phenylhydrazone, 458.
—— ethylacetoacetate, magnetic rotation of, Trans., 809, 837.
—— α-ethylacetoglutarate, 962.
—— ethylideneacetoacetate, magnetic rotation of, Trans., 810, 837.

Ethyl ethylimidoethylphenylthiocarbamate, 466.
—— ethylurethanophenylacetate, 469.
—— formylacetate, acetyl and benzoyl derivatives of, 817.
—— —— constitution of, 816.
—— fulminurate, 690.
—— —— isomeric, 1417.
—— fumarate, action of ethyl sodiomalonate on, 590.
—— β-furfuramidocrotonate, 57.
—— hexyl ketone, 35.
—— hippurate, compound obtained by the action of sodium ethoxide on, 1002.
—— hydrazopropionate, 452.
—— hydrogen adipate, dissociation constant of, TRANS., 712.
—— —— camphorate, allo-, 1102.
—— —— dimethylmalonate, dissociation constant of, TRANS., 712.
—— —— ethylmalonate, dissociation constant of, TRANS., 712.
—— —— fumarate, dissociation constant of, TRANS., 714.
—— —— isosuccinate, dissociation constant of, TRANS., 712.
—— —— maleate, dissociation constant of, TRANS., 714.
—— —— malonate, dissociation constant of, TRANS., 711.
—— —— phthalate, dissociation constant of, TRANS., 714.
—— —— sebate, dissociation constant of, TRANS., 713.
—— —— suberate, dissociation constant of, TRANS., 713.
—— —— succinate, dissociation constant of, TRANS., 711.
—— β-hydroxyacrylate, 816.
—— —— hydroxybenzofurfuran-α-methyl-β-carboxylate (para-), 611.
—— β-hydroxycrotonate, acetyl and benzoyl derivatives of, 817.
—— hydroxytoluquinoxalineacetate, 709.
—— imidoethylphenylthiocarbamate, 466.
—— imidophenylthiocarbamate, 466.
—— imidosuccinamate, 820.
—— iodide, preparation of, TRANS., 717.
—— isobutyl ketone, 36.
—— —— —— oxidation of, 36.
—— isocamphorate, 501.
—— isopropyl ketone, 36.
—— itachloropyrotartrate, action of ethyl sodiomalonate on, 591.
—— itaconate, action of ethyl sodiomalonate on, 591.
—— ketacetate, 955.
—— licaryl ether, 1236.
Ethyl malate, inactive, 1431.
—— maleate, action of ethyl sodiomalonate on, 590.
—— malonate nitrosophenylhydrazide, 1004.
—— —— phenylhydrazide, 1004.
—— mandelate, 1089.
—— mesaconate, action of ethyl sodiomalonate on, 591.
—— mesoxalate, 40.
—— methoxybenzoylacetate (ortho-), 844.
—— methyl ketone, chloro-, action of sodium on, 810.
—— —— —— —— reactions of, 810.
—— β-methylacetosuccinate, action of nitrous acid on, 1074.
—— methylamphiglyoximecarboxylate, 1176.
—— methylcamphocarboxylate, 201.
—— 1 : 2-methylcarboxyethylpyrrolineacetate, 144.
—— methyl-α-cyanotricarballylate, 1182.
—— methyldiacetyladipate, TRANS., 73.
—— —— decomposition of, by heat, TRANS., 75.
—— methylsynglyoximecarboxylate, 1175.
—— morphine carbonate, 638.
—— β-naphthalenesulphonate, 1220.
—— β-naphthyl-β-amidoisobutyrate, 1342.
—— α-naphthylamidosuccinate, 860.
—— β-naphthylamidosuccinate, 860.
—— α-naphthylazoacetoacetate, 367.
—— α-naphthylidoacetate, 1341.
—— β-naphthylidoacetate, 1342.
—— α-naphthylidobutyrate, 1338.
—— β-naphthylidobutyrate, 1338.
—— α-naphthylidopropionate, 1337.
—— β-naphthylidopropionate, 1337.
—— nicotenylamidoximecarbonate, 208.
—— nitrate, action of alkaline solutions on, 692.
—— nitrosomethylisostrychnate, 1013.
—— oxalacetate, compound of, with phenylhydrazine, 49.
—— —— reduction of, 147.
—— oxalate, action of phosphoric chloride on, 588.
—— —— diphenylhydrazide, 981.
—— —— α-naphthylhydrazide, 511.
—— —— β-naphthylhydrazide, 509.
—— —— paratolylhydrazide, 512.
—— oximidoacetate, 700.
—— pentaneoctocarboxylate, 1316.
—— phenylacetate, amido-, 214.
—— phenylamidoacetate, 468.
—— —— nitrite, 469.
—— phenyl-β-azocrotonate, 143.

Ethyl phenylbiazolonecarboxylate, 513.
—— phenylcarbamate, nitration of, 712.
—— phenylhippurate, 468.
—— phenylhydrazidopropionate, 1456.
—— phenylhydrazilethylenedicarboxylate, TRANS., 794.
—— phenylhydrazine-β-carboxylate, 145.
—— phenyl-β-hydrazocrotonate, 142.
—— phenylhydrazoneketophenylpyrazolonecarboxylate, 458.
—— phenylmethylpyrazolonecarboxylate, 798.
—— phenyl-β-naphthylcarbamate, 166.
—— phenylpyrazolonecarboxylate, TRANS., 794, 798.
—— phenyltartronate, 40.
—— phenylthiouranilidacetate, 468.
—— phenyluramidoacetate, 468.
—— phenyluranilidacetate, 468.
—— piperazyloxamate, 211.
—— propanetetracarboxylate, 41.
—— propyl ether, 28.
—— —— ketone, oxidation of, 35.
—— quinoneoximecarboxylate, 1457.
—— santonate, amine of, 1353.
—— —— hydrazide of, 1353.
—— —— oxime of, 1352.
—— sodacetoacetate, 1428.
—— —— action of ethereal salts of unsaturated acids on, 590.
—— —— action of ethyl chlorocarbonate on, 1070, 1178.
—— —— constitution of, 140, 1178.
—— sodethylmalonate, action of acetic chloride on, 1179.
—— sodiocyanacetate, action of ethyl salts of unsaturated acids on, 1181.
—— sodiocyanotricarballylate, 1181.
—— sodiomalonate, action of ethereal salts of unsaturated acids on, 590.
—— sodium acetothiosulphate, 1419.
—— succinate phenylhydrazine, 1495.
—— succinic chloride, 1495.
—— tannacetoacetate, 181.
—— tetrachloro-α-hydroxyhydrindenecarboxylate, 858.
—— tetrahydroxysuccinate, 1181.
—— toluenesulphonate (para-), 1220.
—— toluidoacetate (ortho-), 1334.
—— —— (para-), 1335.
—— toluidoacrylate (β-para-), 818.
—— toluidobutyrate (α-ortho-), 1338.
—— —— (α-para-), 1338.
—— —— (β-para-), 818.
—— toluidopropionate (α-ortho-), 1337.
—— —— (α-para-), 1337.
—— tolylbiazolonecarboxylate (para-), 513.
—— triacetylacetate, 145.
—— trichloroparahydroxybenzofurfuran-α-methyl-β-carboxylate, 609.
Ethyl trichloroquinolacetoacetate, 608.
—— trichloroquinoneacetoacetate, 608.
—— trinitrophenylenedimalonate nitrite, 1219.
—— trithioacetate, 154.
Ethyl-γ-acetobutyric acid, γ-, 962.
Ethylacetovanillone, 61.
Ethylacetovanillonoxime, 61.
Ethylacetylacetone, magnetic rotation of, TRANS., 813, 851.
Ethylacetylene, α-hydrobromide, 127.
Ethylacridine, 342.
Ethylaldoxime, action of azotoluene on, 1079.
—— action of diazobenzene on, 1079.
Ethylamidometanitrobenzophenone, para-, 336.
Ethylamidophenylnaphthylamine, action of benzaldehyde on, 1472.
Ethylamine hydrogen diaminechromium thiocyanate, 1000.
—— platinothiocyanate, 286.
—— thio-, salts of, 130.
—— thio-derivatives of, 130.
Ethylanilbiguanidine, 357.
Ethylaniline, action of silicon tetrachloride on, TRANS., 455.
Ethylantibenzhydroximic acid, 463, 464.
Ethylbenzanilide, para-, 488.
Ethylbenzene, action of aluminium chloride on, 1309.
Ethylbenzenylamidine, 53.
Ethylbenzhydroximic acids, 462.
Ethylbenzophenone oxime, antipara-, 488.
—— —— synpara-, 488.
Ethylbenzoylcarboxylic acid, orthodichloronitro-, 1229, 1232.
—— —— —— lactone of, 1230.
Ethylbergaptic acid, 72.
Ethyl-δ-caprolactone, γ-, 962.
Ethylchitenidine, 1250.
Ethylcinnamylamide, β-brom-, 215.
Ethylcoumarin, α-, derivatives of, 330.
Ethylcoumarinic dibromide, 989.
Ethylcrotonic acid, oxidation of, 958.
Ethylcysteïn, 1111.
Ethyldimethylamidobenzene (6:1:4:3), TRANS., 420.
Ethyldithiobiuret, α-, 704.
Ethylene, absorption coefficient of, in water and in alcohol, 1044.
—— action of heat on, TRANS., 329.
—— explosion of, with less than its own volume of oxygen, TRANS., 873.
—— flame, experiments on, TRANS., 210.
—— glycol, thermochemistry of, 764.
—— nitrate, action of alkaline solutions on, 692.

Ethylene paratoluenethiosulphonate, 990.
—— sodium thiosulphonate, 1418.
Ethylenebenzenyldiamine, 1248.
Ethylene-derivatives of diazoamido-compounds, Proc., **1892**, 119.
Ethylenediamine, action of dithio-oxamide on, 1247.
—— action of, on thiamides, 1247.
—— platinothiocyanate, 287.
Ethylenephenylhydrazone, thionyl-, 1324.
Ethyleuxanthones, 1355.
Ethylfurfurylcarbamide, 43.
Ethylfurfurylthiocarbamide, 43.
Ethylhydroberberine, derivatives of, 1499.
Ethyl-δ-hydroxycaproic acid, salts of, 962.
Ethylhydroxypyrimidinecarboxylic acid, 1008.
Ethylidene bromide, bromination of, 1414.
Ethylideneacetophenone, trichlor-, 695.
Ethylidenecinchonic acid, 1490.
Ethylidenecinchoxinic acid, 1490.
Ethylidenedicyanophenylhydrazine, 597.
Ethylidenediphenylhydrazone, 1196.
Ethylisobutylthiocarbamide, symmetrical, 702.
Ethylisoformanilide, 708.
Ethylisosuccinimide, 701.
Ethylmalonic acid, bromo-, 40.
Ethylmercaptophthalimide, action of various reagents on, 130.
Ethylmetanitrobenzamide, β-brom-, 213.
Ethylmetanitrobenzenylamidine, 52.
Ethylmetaxylene, symmetrical, and its derivatives, 969.
—— unsymmetrical, and its derivatives, 968.
Ethylmethylamine, 64.
Ethylmethylketoxime, action of hydrocyanic acid on, 1196.
Ethylmethylmaleïc acid, 814.
Ethylmethylquinoline, 1107.
Ethyl-β-naphthindolesulphonic acid, sodium salt of, 1458.
Ethyl-β-naphthoxindole, 1458.
Ethylorthotoluidine, paramido-, 1078.
Ethylparisopropyltoluene, ortho-, 985.
Ethylphenol, ortho-, 1318.
Ethylphenylacetamide, β-brom-, 214.
Ethylphenylhydrazine acetoacetate, action of hydrocyanic acid on, 1196.
Ethylpseudocumene and its derivatives, 990.
Ethylpyridine, β-, properties and derivatives of, 629.
Ethyl-α-pyridone, 209.
Ethylpyrroline, α-, 351.
Ethylpyrroline, β-, 352.
Ethylpyrrolines, constitution of, 350.
Ethylquinidine, 1250.
Ethylquinolone, bromo- and nitro-derivatives of, 879, 880.
Ethylresorcinol ethyl ether, nitroso-, 45.
Ethylsulphone, diamido-, 131.
Ethylsulphonediphthalamic acid, 131.
Ethylsynbenzhydroximic acid, 463, 464.
Ethylthiobiuret, α-, 703.
Ethylthiocoumarin, α-, 330.
Ethylthiophen, β-, 829.
Ethylthiophenhydroximic acid, 831.
Ethylthiourea, action of nitrous acid on, Trans., 525.
Ethyltricarballylic acids, α-, 42.
Ethyltrihydroxybenzene, dinitro-, 315.
Ethylytrimethylammonium dibromo-, salts of, 806.
—— —— tribromo-, salts of, 807.
—— —— β-iodo-, salts of, 808.
Ethyltrimethylbenzenesulphonic acids, 990.
Ethyltrimethylenedisulphonesulphide, 593.
Ethyltrimethylenetrisulphone, 591, 593.
Ethylurethanophenylacetic acid, 469.
Ethylvinylpyridine, 1358.
Ethylxylenes, amido-, 969.
Ethylxylenesulphonic acids, 969.
Eucalyptus oil, terpin hydrate from, 1235.
Eupatorin, 1103.
Eupatorium perfoliatum, active principle of, 1103.
Eurhodoles, 859.
Euxanthic acid, 1354.
—— —— action of hydroxylamine on, 1355.
Euxanthone, 1354.
—— constitution of, 504.
Evaporation and condensation, spheres of, 956, 1149.
—— latent heat of, relation of specific inductive capacity to, 258.
—— under reduced pressure, apparatus for, 1386.
Excretion, nitrogenous, influence of water and sodium chloride on, 904
—— of nitrogen and uric acid from the human system, influence of hot baths on, 1503.
—— of nitrogen in kidney disease, 743, 1504.
—— of nitrogen in urine, 1503.
Expansion of water, 7, 106, 1382.
—— thermal, of liquid bismuth, 259.
Explosion of ammonium nitrate, 683.
Explosives, 1141.
Extract, nitrogen free, constituents of, 653.
Extraction apparatus, 910.

F.

Fat, estimation of, in yolk of eggs, 1134.
—— estimation of, in milk, 549, 550, 1134, 1532.
—— estimation of, in the products from milk, 391.
—— extraction of, from milk solids, 391.
—— horse, 1533.
Fat-decomposing ferments in plants, 1261.
Fat-oils, absorption and digestion of, by plants, 1118.
Fats and oils, revision of constants employed in the analysis of, 547.
—— estimation of unsaponifiable matters in, 1533.
—— foreign, detection of, in butter, 1532.
Fauserite from Hodrusbánya, 1054.
Fenchelenamine, 1240.
Fenchelenic acid and its derivatives, 1237.
—— —— reduction of, 1237.
Fenchone and camphor series, 1236.
Fenchonitrile and its derivatives, 1236.
Fenchylamine fenchylcarbamate, 1239.
—— salts, 1239.
Fenchylcarbamide, 1239.
Fenchylphenylthiocarbamide, 1239.
Ferment, aërobic nitrate-reducing, in straw, 1259.
—— fibrin, 1112.
—— saccharific, localisation of, 517.
Fermentation, 820.
—— alcoholic, influence of oxygen and concentration on, TRANS., 369.
—— —— influence of the hydrolytic action of yeast on its power of, TRANS., 940.
—— conditions affecting the action of fluorides on, 906.
—— of arabinose with the *Bacillus ethaceticus*, TRANS., 737.
—— of blood, 900.
—— of farmyard manure, 1123.
—— of mannitol and dextrose with *Bacillus ethaceticus*, TRANS., 432.
—— of mannitol and dulcitol, a pure, TRANS., 254.
Ferments, digestive, in crustacean eggs, 362.
—— fat-decomposing, in plants, 1261.
—— in pineapple juice, 650.
—— unorganised, 899.
Fern extract, ethereal, poisonous constituent of, 380.
Ferric chloride, action of barium peroxide on, 408.
—— —— action of, on metallic sulphides, 18, 278.
Ferric hydroxide, colloïdal solutions of, TRANS., 152, 162.
—— oxychlorides, crystallised, 119.
—— phosphate, dissociation of, in presence of water and of saline solutions, 1292.
—— sulphate, anhydrous, crystallised, 943.
Ferrous solutions, action of iron on, 276.
Ferrum reductum, estimation of metallic iron in, 1524.
Fibre, vegetable, detection of, in silk or woollen tissue, 667.
—— —— woody, the pentosans of, 1420.
Fibres, specific gravity of, 1036.
Fibrin, decomposition of, in the human body, 904.
—— solubility of, 897.
Fibrin-ferment, 1112.
Fibrin-peptone, 1500.
Ficus carica, the latex of, 653.
—— *rubiginosa* and *F. macrophylla*, resins of, TRANS., 916.
Filicic acid, 380.
Filicin, 380.
Filtration, hot, apparatus for, 1150.
—— use of asbestos in, 751.
Fir-wood, dextrose from, 801.
—— so-called artificial pectic acid from, 827.
Flame, coal-gas, flat, temperature of various parts of, TRANS., 326.
—— structure of, TRANS., 331.
Flame-coloration, origin of, PROC., **1892**, 8.
Flames, coal-gas, carbon deposited from, PROC., **1892**, 46.
—— —— —— luminosity of, TRANS., 322.
—— luminous, structure of, TRANS., 217.
—— non-luminous, experiments on, TRANS., 205.
—— optical proof of the existence of suspended matter in, 111.
—— origin of acetylene in, PROC., **1892**, 47.
—— structure and chemistry of, TRANS., 204.
—— the interactions occurring in, PROC., **1892**, 22.
Flashing points of heavy mineral oils, determination of, 542.
Flavin, preparation of, 503.
Fluoran, 970.
—— constitution of, 1228.
—— tribromo-, 970.
Fluoresceïn, constitution of, 1228.
Fluoresceïn-group, 1228.
Fluorescence, appearance of, in quinine salts, TRANS., 789.

Fluorescin, 970, 1319.
—— ethyl ether, 1319.
Fluorides, action of boron on, 1153.
—— estimation of silicic acid in, 1127, 1128.
—— influence of, on fermentation, 906.
Fluorine, estimation of, 911.
—— in natural phosphates, 1055.
—— in recent and fossil bones, 1161.
—— place of, in the classification of the elements, 11.
—— proportion of, in fossil bones of various ages, 1413.
Fluoroform, 1316.
Fluoroline, 1492.
Fluorosulphonic acid, Trans., 921.
Fluorovanadites, 785.
Fluoroxyhypovanadates, 785.
Fluoroxyvanadates, 785.
Fœtal organism, iron in the, 1502.
Fœtus, intake of the iron by the, 516.
Food, constituents, calorific value of, 4.
—— value of brushwood, 1511.
—— —— of the cotton plant, 1510.
Footeite, 415.
Formaldehyde, 423, 1423.
—— action of, on orthodiamines, 1496.
—— condensation products with, 1450.
—— nutrition of green plant cells with, 1259.
—— reactions of, 579.
—— thio-, reactions of, 579.
Formamidine picrate, 705.
Formanilide, action of trimethylene chlorobromide on, 1491.
—— metanitro-, 706.
Formates, metallic, 140.
—— trithiortho-, 611, 850.
Formic acid, heats of combustion and formation of, 1139.
—— —— thio-, 421.
Formoguanamine, formation of, 736.
Formohydroxamic acid, 699.
Formotoluidides, action of trimethylene chlorobromide on, 1491.
Formyl compounds, aromatic, derivatives of, 707.
Formyldiorthotolylhydrazine, 843.
Formyldiparatolylhydrazine, 843.
Formyldiphenylhydrazine, 843.
Formylorthotolylhydrazine, 843.
Fouqueite, 1056.
Frangulin, Trans., 1.
—— composition of, Trans., 3.
—— hydrolysis of, Trans., 4.
—— preparation of, Trans., 1.
Fraxetin, constitution of, 628.
Fraxin, constitution of, 628.
Freezing points, determination of, 765.
—— —— of cadmium, bismuth, and lead, lowering of the, when alloyed with other metals, Trans., 888.
Freezing points of dilute solutions of cane sugar, 678, 1046.
—— —— of isomorphous mixtures, 396.
—— —— of very dilute solutions, determination of, 935.
Friedel-Crafts' synthesis, 337, 594.
Friedelite from Sweden, 1405.
Frog muscle, excitability of, in salt solutions, 515.
Fructose, d-, thermochemistry of, 763.
Fucose, thermochemistry of, 763.
Fulminuramide, 1417.
Fulminuric acid, 690, 1417.
Fumarates and maleates, action of *Penicillium glaucum* and *Aspergillus niger* on, 820.
Fumaric acid, complete transformation of, into maleïc acid, 1306.
—— —— transformation of maleïc acid into, 1305.
—— —— thermochemistry of, 1041.
Fungi, formation and physiological significance of oxalic acid in, 230.
Furfuraldehyde, condensation products of, with bases, 1451, 1452.
—— estimation of, 388.
—— estimation of, in spirits, 245.
—— formation of, from glycuronic acid derivatives and from albumin, 1433.
—— oximes of, 1433.
—— thio-, Cahours' polymeride of, 301.
—— *α*-trithio-, 301.
—— *β*-trithio-, 301.
Furfurallevulinic acid, *δ*-, 147.
Furfuramidine hydrochloride, 1006.
Furfuran compounds, 1006.
Furfuraniline, 1452.
Furfurantialdoxime, 1434.
Furfurimidoethyl ether, 1006.
Furfuronitrile, 831.
Furfuropinylamine, 997.
Furfursynaldoxime, 1433.
—— compound of, with phenyl cyanate, 1434.
Furfurylamine, 43.
—— nitro-, 43.
Furfurylcarbamide, 43.
Furfurylguanidine salts, 43.
Furfurylthiocarbamide, 43.
Furnace, combustion, new, 1514.
Furyl cyanide, 1006.
Furyldimethylhydroxypyrimidine, 1007.
Furylhydroxypyrimidinecarboxylic acid, 1007.
Furylmethylbenzylhydroxypyrimidine, 1007.
Furylmethylhydroxypyrimidine, 1006.
Furylphenylhydroxypyrimidine, 1007.
Fusel oil, estimation of, in spirits, 244, 543.

G.

Gadolinite, 1410.
Gadolinium earth, 1400.
Galactan, β-, 1171.
Galactonic acid, i-, 825.
—— —— l-, 826.
—— —— polarisation phenomena of, 1432.
Galactonolactone, polarisation phenomena of, 1432.
Galactose, i-, 826.
—— l-, 826.
—— thermochemistry of, 763.
Galena, analysis of, 662, 663, 1522.
—— estimation of sulphur in, 658.
—— separation of lead, silver, and zinc in, 1378.
Galipidine, 643.
Galipine, 642.
Galleïn, acetyl derivatives of, 1319.
Gallic acid, conversion of, into pyrogallol, 1314.
—— —— derivatives of, 715.
—— —— estimation of, in barks, 390.
—— —— estimation of, in urine, 924.
—— —— physiological action of, 904.
Gallium, spectrum of, 930.
Gallotannic acid, estimation of, in barks, 390.
Galvanic cell, practical form of the Latimer-Clark standard, 669.
—— —— standard, for small differences of potential, 670.
—— polarisation at small electrodes, 759.
Gambier, analysis of, 928.
Ganophyllite from Harstigen Mine, Sweden, 1412.
Garcinia mangostana, rind of, 205.
Garnierite from Norway, 1409.
Gas absorptions, improved pipette for, 1124, 1374.
—— analysis apparatus, clamps for, 524.
—— batteries, E.M.F. of, 393.
—— coal-, flame, experiments on, Trans., 205, 210.
—— —— flameless incandescence produced by, 768.
—— —— flames, carbon deposited from, Proc., **1892**, 46.
—— —— —— luminosity of, Trans., 322.
—— —— formation of ammonium sulphate by burning, 1389.
—— —— formation of sulphuric acid in burning, 1151, 1374, 1389.
—— —— heats of combustion of, 396.
—— compressed, pyrogenic hydrocarbons in, 797.
Gas pipette, improved, 1124, 1374.
—— water-, action of, on iron, Proc., **1891**, 126.
Gaseous mixtures, slow combustion of, 938.
Gases, absorption coefficients of, 1043.
—— absorption of, by liquids, 556.
—— determination of the specific gravity of, 1267.
—— diffusion of, lecture experiment on, 562.
—— dissolved in water, extraction of, 1526.
—— effusion of, lecture experiment on, 1150.
—— evolved in the fermentation of mannitol and dulcitol, Trans., 259.
—— heat of dissolution of, in liquids, 1042.
—— liquefied, determination of the density of, and of their saturated vapours, 934, 1043.
—— of peptone blood, 363.
—— solubility of, in water, 107, 271.
Gasometric investigations, levelling instrument for, 400.
Gasometry, use of potassium ferricyanide in, 526.
Gastric digestion, influence of amido-acids on, 742.
—— juice, estimation of hydrochloric acid in, 97.
Gas-volumeter, Proc., **1891**, 171.
Gas-volumetric analysis, 538.
Gelatin, decomposition of, in the human body, 904.
Genipa brasiliensis, crystalline constituent of, 1509.
Gentiana verna, substances contained in the petals of, 205.
Gentiol, 205.
Germination, action of boric acid on, 651.
—— of seeds, influence of vegetable poisons on, 228.
Gismondine from Westphalia, 1056.
Glanders, ptomaïne of, 1258.
Glass, action of superheated water and solutions of alkalis and of salts on, 1401.
—— action of water on, 120.
—— adhesion of mercury to, in presence of halogens, Trans., 452.
—— graphical chemistry of, 1158.
—— of slides and cover glasses, influence of the composition of, on the durability of microscopic objects, 1276.
—— solubility of, in cold water, 277.
—— suitable for chemical purposes, composition of, 410, 411, 1052.
—— wool, presence of lead in, 1375.

Glauber's salt, from the potash mines at Kalusz, 1286.
Glaucine, 893.
Glucoheptitol, α-, 1167.
Glucoheptonic acid, α-, 1166.
—— —— β-, 1168.
—— lactone, β-, 1168.
Glucoheptose, α-, 1166.
—— osazone, α-, 1167.
—— phenylhydrazone, α-, 1167.
Glucoheptose, β-, 1168.
—— phenylhydrazone, β-, 1168.
Gluconic acid, polarisation phenomena of, 1432.
Gluconolactone, polarisation phenomena of, 1432.
Glucononic acid, 1170.
Gluconononitol, 1170.
Glucononose, 1170.
Gluco-octitol, α-, 1170.
Gluco-octonic acid, α-, 1169.
—— ——β-, 1170.
Gluco-octose, α-, 1169.
—— phenylhydrazone, 1169.
Glucosamine, benzoyl derivatives of, 134.
Glucose, action of acetic anhydride on, 1293.
—— formation of, in the organism, 517.
Glucose, d-, thermochemistry of, 763.
Glucose. See also Dextrose.
Glucose-series, ascent of the, 1164.
Glutaconic acid, tetrachloro-, 1463.
Glutamic acid and its derivatives, 298.
Glutaric acid, action of hydroxylamine on derivatives of, 136.
—— —— decomposition of, at a high temperature, 40, 297.
—— —— pentachloro-, 1186.
—— —— thermochemistry of, 1041, 1141.
Glutarimide, 1484.
Glutarimidoxime, 138.
Glutimide, 298.
Glutin, peptone salts from, 895, 1016.
Glycerol, derivatives of, 288.
—— estimation of, by alkaline permanganate, 544.
—— estimation of, in sweet wines, 1263.
—— estimation of, in wine, 246, 1529.
—— fluorhydrins from, 799.
—— thermochemistry of, 764.
Glycerols, crude, analysis of, 544.
Glyceryl trinitrate, action of alkaline solutions on, 692.
Glycocine and its derivatives, 294.
Glycogen, estimation of, in the blood, 89.
—— formation of, in the liver from various sugars, 902.
Glycol, disodium derivative of, 421.
Glycol, thermal value of the hydroxyl groups in, 576.
Glycolaldehyde, preparation and properties of, 1424.
Glycoline, 633.
Glycollic acid, crystallography of, Proc., **1892**, 72.
—— —— preparation of, Proc., **1892**, 72.
—— anilide, Proc., **1892**, 72.
Glycolysis, hepatic, 89.
—— in blood, 900.
Glycuronic acid derivatives, formation of furfuraldehyde from, 1433.
Glyoxaline, 1493.
—— action of ethyl chloracetate on, 1493.
—— constitution of, 1326.
—— nitro-, 1493.
Glyoxalsulphonic acid, action of amido-bases on the sodium salt of, 1458.
Glyoxalylamidoformic acid phenylhydrazone, 442.
Glyoximecarboxylic acids, dissociation constants of, 1268.
Glyoximedicarboxylic acids, dissociation constants of, 1268.
Glyoximes, aliphatic stereoisomeric, 693.
Gmelinite from Nova Scotia, 21.
Gold, absorption of oxygen by, 943.
—— allotropic states of, 405.
—— and cadmium, compound of, Trans., 914.
—— electrolytic detection of, 541.
—— electrolytic separation of, from arsenic, from molybdenum, tungsten, and osmium, 920.
—— estimation of, by means of hydroxylamine hydrochloride, 662.
—— estimation of small quantities of, in base metals, 1525.
—— hydrosulphide, Trans., 135.
—— lowering of the freezing point of bismuth by, Trans., 897.
—— lowering of the freezing point of cadmium by, Trans., 902.
—— lowering of the freezing point of lead by, Trans., 909.
—— occlusion of hydrogen by, 567.
—— sulphide, natural, 283.
—— sulphides, organosols of, 775.
—— tin and cadmium, estimation of, in alloys, 1030.
—— use of cadmium in assaying, 919.
—— volumetric estimation of, 1526.
Gold. See also Auric.
Gold-bearing hot spring deposit, 24.
Gold-lead alloy, analysis of, Trans., 912.
Grape, chlorophyllic substances of the pericarp of the, 874.

Grapes, green, cause of the acidity of, 589.
Graphite, action of nitric acid on, 406,
—— artificial formation of, 407.
—— varieties of, 565.
Gravimetric analysis, simple and rapid method of, 524.
Gravivolumeter, Proc., **1891**, 171.
Grunerite from Michigan, 793.
Guanamine, synthesis of, 736.
Guanidine, amido-, and its derivatives, 1295.
—— nitrite, 53.
—— nitro-, 579, 951, 1295.
—— —— thermochemistry of, 1142.
—— occurrence of, in plants, 908.
—— picric acid as a reagent for, 950.
—— platinothiocyanate, 287.
—— salts, 1142.
—— test for, 926.
—— thermochemistry of, 1142.
Gulonic acids, i-, 822.
—— —— optically isomeric, 822.
Gulonolactones, 822.
Gulose, i-, 823.
Gum in plants which yields xylose on saccharification, 1371.
Gums which yield xylose, occurrence of, 380.
Guncotton, estimation of calcium and magnesium in, 1520.
Guvacine, 740.
—— nitroso-, 740.

H.

Hæmatin spectrum, sensitiveness of, 1369.
Hæmatite from the Hargita Mountains, 1054.
Hæmatoporphyrin, detection of, in urine, 1136.
—— in urine, 649.
Hæmatoporphyrinuria, 1118, 1506.
Hæmocyanin, 898, 1370.
—— respiratory value of, 1370.
Hæmoglobin, colloïdal solutions of, Trans., 157, 162.
—— colorimetric estimation of, 1264.
—— combination of, with oxygen, 1369.
Halogen salts, double, 779.
Haloïds, mutual displacement of the, 1270.
Haricot beans, cooked, composition of, Trans., 227.
Heat, expansion of water by, 1382.
—— latent, of evaporation, relation of specific inductive capacity to, 258.
—— —— of fusion of aluminium, 1281.
—— —— relation of E.M.F. to, 257.
—— mechanical theory of, recent developments of, 395.
Heat, of dissociation of electrolytes, correction in the calculation of, 931.
—— of dissolution and of osmotic pressure, theory of, 676, 765.
—— —— of gases in liquids, 1042.
—— —— of salts in water, 676.
—— of formation of hydrazine and hydrazoic acid, 261.
—— —— of permolybdic acid, 1383.
—— —— of platinic bromide and its principal derivatives, 3.
—— —— of potassium tricarballylates, 762.
—— —— of salts in alcoholic solution, 262.
—— of neutralisation of pyrogallol, 1446.
—— of vaporisation of a solution, 1382.
—— production in nerves during excitation, 365.
—— reconversion of, into chemical energy by production of water-generator gas and carbonic anhydride-generator gas, 673.
—— specific, of aluminium, 673, 1281.
—— —— of liquids, at temperatures above the boiling point, 761.
—— —— —— calculation of, 2.
—— —— of the diamond, 761.
Heat. See also Thermochemistry.
Heating power of coal, formulæ for calculating, 1143.
Heats of combination of bromine and iodine with magnesium, 762.
—— of combustion and formation of ethyl alcohol, formic acid, and acetic acid, 1139.
—— —— —— of nitrobenzenes, 4.
—— —— of cooked vegetables, Trans., 240.
—— —— of food constituents, 4.
—— —— of products of the distillation of coal, 395.
Heintzite from Leopoldshall, 791.
Helvine from Hungary, 1412.
Hemicelluloses, 907.
Hemipinic acid, meta-, 180.
Hemipinimide, bromo-, 1210.
Henbane seed, constituents of, 231.
Heptacetyl-α-glucoheptitol, 1168.
Heptane flame, experiments on, Trans., 210.
—— refractive power of, at different temperatures, Trans., 294.
Heptine, 1235.
—— action of sulphuric acid on, 967.
—— nature of, 1065.
—— nitrosochloride, 1235.
Heptyl acetate, secondary, 1162.
Hessite from Botes, 1054.
—— from Mexico, 793.

Heulandite- and desmine-groups, relations between minerals of the, 417.
Hexacetyl-α-glucoheptose, 1167.
Hexadecylacetylene, 1164.
Hexadecylene, bromo-, 1163.
Hexahydrobenzoic acid, properties of, 714.
Hexahydrodimethyldiazine, 507.
Hexahydronicotine, 1365.
Hexahydrophthalic acid, dibromotrans, 1216.
Hexahydrophthalic acid, synthesis of, TRANS., 172.
—— acids, thermochemistry of, 1041.
Hexahydropiperidinecarboxylic acid, 85.
Hexahydroxyaurin, 1470.
Hexamethyleneamine, action of ethyl chloracetate on, 1173.
—— action of sulphurous anhydride on, 1173.
—— benzochloride, 1173.
—— derivatives of, 1173.
Hexamethylenetetracarboxylic acid, dissociation constant of, TRANS., 706.
Hexamethyltriamidodiphenyltolylmethane, 190.
Hexamethyltriamidotriphenylarsine, 1321.
Hexane, nitration of, 575.
—— nitro-, 575.
Hexapropyltrimethylenetrisulphone, 592.
Hexenylsulphuric acid, 951.
Hexethyltrimethylenetrisulphone, 591.
Hexylacetylene, normal, 1064.
Homarus vulgaris, blood of, 648.
Homatropine, ψ-, 891.
Homoarecoline, 739.
Homocatechol, 1312.
—— and its nitro-derivatives, 1443.
Homocumic acid, paradibromo-, oxidation products of, 604.
Homogentisic acid, estimation of, in urine, 925.
Homolevulinic acid, 961.
Homologous compounds, vapour tension of, 396.
Homonapelline, TRANS., 393.
Homoparahydroxybenzaldehyde, ortho-, 320.
Homoparahydroxybenzaldoxime, ortho-, 320.
Homoparahydroxybenzenylamidoxime, ortho-, 320.
Homparahydroxybenzonitrile, ortho-, 320.
Homoparahydroxybenzophenylhydrazone, ortho-, 320.
Homopiperonic acid, α-, 47.
Homosalicenylamidoxime, ortho-, 320.
—— para-, 319.
Homosalicylaldehyde, ortho-derivatives of, 320.
Homosalicylaldoxime, ortho-, 320.
—— para-, 318.
Homosalicylamide, para, 318.
Homosalicylic acid, para-, derivatives of, 318.
Homosalicylonitrile, ortho-, 320.
—— para, 319.
Homosalicylphenylhydrazone, ortho-, 320.
Homosalol, 1092.
Horse fat, 1533.
Hübnerite, 793.
Human *succus entericus*, 1368.
—— system, influence of hot baths on the excretion of nitrogen and uric acid from the, 1503.
—— urine, normal, reducing agents in, 1503.
Humic acid, properties of, 1373.
—— —— spontaneous oxidation of, 655.
Humin, properties of, 1373.
Hungarian minerals, 1054.
Hydantoïns and bases derived from them, 149.
—— γ-substituted, 827, 828.
Hydracetine, paralkyloxy-derivatives of, 1080.
Hydrastine, 223.
—— reactions of, 755.
Hydrazides, 843, 981.
—— acid, 710.
Hydrazine, heat of formation of, 261.
—— hydrate, molecular refraction of, 934.
—— nitride, 113.
—— thermochemistry of, 933, 1143.
Hydrazineamidoditolyldisulphonic acid, 1468.
Hydrazine-residue, displacement of, by halogens, 842.
Hydrazines, aromatic, action of the chlorides of phosphorus, arsenic, boron, and silicon on, 1324.
—— of quinoline, TRANS., 782.
—— secondary asymmetrical, 456.
Hydrazobenzenedisulphonamide, 973.
Hydrazobenzeneorthocarboxylic acid, 67.
—— —— parachlor- and parabrom-, 68.
Hydrazo-compounds, intramolecular change in, 840.
Hydrazodicarbonamide, 1298, 1429.
Hydrazodicarbonamidine nitrate, 1298.
Hydrazoic acid, heat of formation of, 261.
Hydrazomethylethylisoxazole, 79.
Hydrazones, action of hydrocyanic acid on, 1195.
—— aromatic, and thionyl chloride, 1324.

Hydrazones, isomeric, 1083.
Hydrazoorthodichlorodibenzyl alcohol, 444.
Hydrazophenetoïl, para-, 159.
Hydrazopropionylhydrazine, 452.
Hydrazotoluene, para-, formation of an orthamidotolylamine from, 853.
Hydrazotoluenedisulphonamide, 1468.
Hydrindone, formation of derivatives of, from halogen cinnamic acids, 1222.
—— orthobrom-, 1222.
—— parachlor-, 1222.
—— paraiodo-, 1222.
Hydriodic acid and hydrogen peroxide, catalytic influence of acids on the velocity of the reaction between, 110.
Hydriodoapoquinine, 82.
Hydriodoquinine, 82, 640.
Hydroantipyrine, 731.
Hydrobenzoic acids, 714, 847.
Hydroberberine, 1498.
—— ethiodide and related compounds, 1499.
Hydrobromic acid, preparation of, 270.
—— —— pure, preparation of, TRANS., 97.
Hydrobromic acid. See also Hydrogen bromide.
Hydrocarbon derived from perseïtol, 1065.
Hydrocarbons and their halogen derivatives, saturated and unsaturated, method of determining the constitution of, 285.
—— aromatic, action of aluminium chloride on, 1309.
—— —— displacement of hydrogen by haloïds in, 1310.
—— closed-chain, action of sulphuric acid on, 967.
—— decomposition of, with steam, 288.
—— flames of, TRANS., 204, 210, 212.
—— of the methane series, nitration of, 575.
—— pyrogenic, in compressed gas, 797.
—— unsaturated, and phenols, condensation of, 446, 1443.
—— vegetable, natural synthesis of, 1234.
Hydrochelidonamic acid, 432.
Hydrochelidonanilic acid, 433.
Hydrochelidon-bismethylimide, 433.
Hydrochelidonic acid, 432.
—— —— dioxime, 434.
Hydrochelidonimide, 433.
Hydrochloric acid, estimation of, in stomach contents, 326, 1125.
—— —— estimation of, in the gastric juice, 97.
—— —— free, in the stomach, estimation of, 236.
Hydrochloric acid tables, revised, 11.
Hydrochlorodimethylpyrone, 811.
Hydrochloro-α-methyltropidine, 358.
Hydrocinnamenylacrylic acid, 988.
—— —— oxidation of, 986.
Hydrocinnamic acid, parachlor-, 1222.
Hydrocotoïn, reactions of, 62.
Hydrocoton, nature of, 873.
Hydrocoumarone, 1318.
Hydrodiffusion, theory of, 935.
Hydrofluoranic acid, 1228.
Hydrogen, absorption coefficient of, in alcohol, 1043.
—— and oxygen, admixed, slow combustion of, 562, 938.
—— behaviour of, towards lead and other metals, 567.
—— bromide, action of sulphuric acid on, TRANS., 99, 100.
—— cyanide, action of, on mercurous salts, 1416.
—— —— detection of, 361.
—— —— estimation of, 1530.
—— flame, experiments on, TRANS., 215.
—— Hasselberg's so-called second or compound spectrum of, 1381.
—— maximum tension with which, is set free from solutions by metals, 561.
—— nitride, synthesis of, 1151.
—— occlusion of, by lead, 942.
—— —— by metals, 567.
—— —— by palladium, lecture experiment, 563.
—— peroxide, action of iodine and its oxy-acids on, 539.
—— —— action of, on magnesium, 17.
—— —— action of, on the hydrated oxides of cadmium, zinc, and magnesium, 1278.
—— —— and hydriodic acid, catalytic influence of acids on the velocity of the reaction between, 110.
—— —— and potassium permanganate solutions, reaction between, 277.
—— —— detection of, 1124.
—— —— estimation of, 526.
—— —— separation of metals in alkaline solution by, 537.
—— —— solutions, preparation of, 270.
—— —— test for, 381.
—— —— use of, in analysis, 1031.
—— phosphide, action of, on an ethereal solution of bismuth tribromide, 279.
—— reaction of, with chlorine and oxygen, 1147.
—— solubility of, in water, 108.
—— sulphide, absorption coefficient of, in water, 1044.

Hydrogen sulphide flame, experiments on, TRANS., 216.
—— structure of, 1381.
Hydrolopachol, chlor-, TRANS., 631.
—— dibromo-, TRANS., 643.
Hydrolytic action of yeast, velocity of, TRANS., 928.
Hydronaphthoic acids, 191.
Hydrophthalic acids, 1211.
Hydrosorbic acid, oxidation of, 959.
Hydrosulphides, metallic, TRANS., 114.
Hydrotannic acid, 181.
Hydroxamic acid derivatives, isomeric, 711.
—— acids, 461.
—— —— aliphatic, new method of preparing, 698.
—— —— constitution of, 300, 461.
—— —— of the fatty acids, 828.
Hydroximic acids, 462.
Hydroximidomethylsynoxazolone, 1175.
Hydroximidophenylsynoxazolone, 1177.
Hydroxy-γ-acetoisovaleric acid, β-, 325.
Hydroxyacetophenone and its derivatives, 845.
Hydroxyacetylpæonol, 846.
Hydroxy-acids and lactones, reciprocal transformations of, 1303.
—— —— α-, and orthodiamines, constitution of the compounds obtained from, 1359.
Hydroxyaldehydes, ortho-, action of acetic chloride on, 1458.
Hydroxyamidobenzophenone, 1227.
Hydroxyamidothymoquinone, 1098.
Hydroxyanthranol, 346.
Hydroxyaurin, 1469.
Hydroxyaurincarboxylic acids, 1469.
Hydroxyaurindicarboxylic acid, 1469.
Hydroxyaurins and their carboxylic acids, 855.
Hydroxyazo-dyes, ortho-, constitution of, 506.
Hydroxybenzaldiphenylmaleïde, 483.
Hydroxybenzenes, condensation of, with nitrobenzaldehydes, 621.
Hydroxybenzofurfuran-α-methyl-β-carboxylic acid, trichloropara-, 609.
Hydroxybenzoic acids, action of heat on, 1208.
Hydroxybenzophenone, 309.
—— meta-, and its oximes, 490.
—— para-, and its oximes, 489, 490.
Hydroxybenzylidenefenchylamine, 1239.
Hydroxybenzylideneorthamidophenol, 1451.
Hydroxybenzylideneparamidophenol, 1451.
Hydroxybenzylidenepinylamine, para-, 997.
Hydroxy-β_1-bromo-γ_1-methyljuloline, α_1-, 497.
Hydroxybutanedisulphonic acid, 424.
Hydroxybutane-β-sulphonic acid, sodium salt of, 424.
Hydroxybutyric acid, α-chloro-β-, 295.
—— —— β-chlor-α-, 296.
—— —— γ-trichloro-β-, 429.
—— —— γ-, transformation of, into its lactone, 1303.
Hydroxycaprolactone, 959.
Hydroxycarbon compounds, action of non-metallic nitrides and hydronitrides on, 1311.
Hydroxy-3-chloroquinoline, 4-, 877.
—— methohydroxide, 1-, 878.
Hydroxycinnoline, 1494.
Hydroxydimethylquinoline, 729.
Hydroxydinitrodiphenylamine, 310.
Hydroxydiphenylquinoxaline, para-, 733.
Hydroxyditolyldisulphonic acid, amido-, 1468.
Hydroxydixanthones, 504, 1097.
Hydroxyethyl sodium thiosulphate, 1418.
Hydroxyethylbenzoic acid, orthochloronitro-, lactone of, 1230.
Hydroxyglutaric acid, β-, 147.
Hydroxyhydrindenecarboxylamide, tetrachlor-α-, 858.
Hydroxyhydrobenzoïns, diortho-, isomeric, 167.
Hydroxyhydrocyanomesitenelactone, 325.
Hydroxyhydroisohydracetic acid, nitrile of, 325.
Hydroxyhydrolapachol, TRANS., 628.
Hydroxyisoquinolines and their derivatives, 877.
Hydroxyketone-dyes, 1224.
Hydroxyketones, aromatic, 62.
—— —— behaviour of, with sulphuric acid and with ammonia, 1226.
Hydroxylamine, alkyl derivatives of, 316, 1456.
—— constitution of, 1392.
—— crystallised, preparation of, 771, 1391.
—— preparation and properties of, 402, 1391.
—— thermochemistry of, 1143.
Hydroxylamine-derivatives, so-called physically isomeric, 711.
Hydroxy-β-lapachone, TRANS., 649.
Hydroxymetamethoxybenzoylcarboxylic acid, para-, 64.
Hydroxymetanitrobenzaldehyde, para-, 336.
Hydroxymethylbenzoic acid, ortho-, 715.
—— —— rate of transformation of, into phthalide, 1270.
Hydroxy-γ_1-methyl-$\beta_1\gamma_1$-dibromojuloline, α_1-, 497.

Hydroxymethyleneacetone, stereoisomerism of, 1073.
Hydroxy-γ_1-methyljuloline, α_1-, 497.
Hydroxymethylquinoline, metamid-ortho-, 506.
Hydroxymethylquinolines, 727, 728.
—— nitro-, 727, 728, 729.
Hydroxy-α-naphthaquinone, preparation of, 1098.
Hydroxynaphthoïl anilide, β-, 1476.
Hydroxy-β-naphtho-xanthone, 3′-, 1099.
Hydroxynaphtho-xanthones, 1100.
Hydroxynaphthyl trihydroxyphenyl ketone and its derivatives, 1226.
Hydroxynitrobenzyldiphenylmaleïde, 485.
Hydroxynitrobenzyldiphenylmaleïmidine, 486.
Hydroxynitroquinoline [1 : 4-], 1105.
Hydroxyoxindole chloride, amido-, 1219.
Hydroxyphenanthrazine, para-, 733.
Hydroxyphenanthridine, 197.
Hydroxyphenonaphtho-xanthone, 1099, 1100.
Hydroxyphenylhydrindone, 1221.
—— hydrazone, 1221.
Hydroxyphenylhydrocoumarin and its isomerides, 849.
Hydroxyphenylpyridone, $\beta\beta$-dichloro-α-, 449.
Hydroxyphenylpyridonecarboxylic acid, $\beta\beta$-dichloro-α-, 448.
Hydroxypiazthiole, para-, 734.
Hydroxypimelic acid, 428.
Hydroxypiperidine, α-, 1485.
Hydroxypropenylamidoxime, β-trichloro-α-, 321.
Hydroxypropylparadibromobenzoic acid, 604.
Hydroxy-β-phthalimidoethyl sulphide, β-, 130.
Hydroxypyridine, α-, 208.
Hydroxypyruvic acid, osazone of, 356.
Hydroxyquinoline, 4 : 1-brom-, 354.
—— 4 : 3 : 1-dibrom-, 354.
—— 1-, methohydroxide, 878.
—— 2-, methiodide, methochloride, and methohydroxide, 876.
—— 4 : 3-brom-, 353.
Hydroxyquinolines, halogen alkyl compounds of, 876.
Hydroxyquinones, 1098.
—— formation of, from quinones, 45.
Hydroxyquinoxaline, para-, 732.
Hydroxytetrahydrobenzyldimethylamine, Δ^3-, 359.
Hydroxytetrahydronaphthoic acid, bromo-, lactone of, 193.
Hydroxytetramethylenecarboxylic acid, Trans., 44.
Hydroxythymoquinone, 1098.
Hydroxy-$\beta_1\beta_1\gamma_1$-tribromo-γ_1-methyljulolidine, α_1-, 498.
Hydroxyvaleric acid, γ-, transformation of, into its lactone, 1303.
Hydroxyvalerolactone, 958.
Hydroxyxanthones, 504, 1096, 1100.
—— of the naphthalene and quinoline series, 1098.
Hyoscine, 1255, 1366, 1498.
—— composition of, 1498.
Hyoscyamine, existence of, in the lettuce, Trans., 90.
Hypophosphates, 403.
Hyposantonic acid, 870, 1353.
Hyposantonin, 870.
Hypoxanthine, 220.

I.

Imidazole, 313.
Imidazoles, 1326.
Imidazolone, μ-, 1327.
Imidazolyl mercaptan, μ-, 1328.
——.methyl sulphide, μ-, 1328.
Imides, substituted, modes of formation of, 1204.
Imidoacetates, constitution of, 982.
Imidodiazoles, 313.
Imidole, 312.
Imidosulphonamide, Trans., 952.
Imidosulphonates, Trans., 943.
Imidosulphonic acid, Trans., 945.
—— acids, 700.
Imidothiocarbamates, 465.
Inanition, bile during, 225.
Incandescence, flameless, produced by coal gas, 768.
Indazole-derivatives, 67.
Indigo-blue, products from, 991.
Indigodisulphonic acid, synthesis of, 69.
Indigo-green, 991.
Indium hydrosulphide, Trans., 134.
Indole, nitroso-, molecular weight of, 67.
—— synthesis of, from tartaric acid and aniline, 66.
Indoles, substituted, formation of, 1465.
Indothymol, 1311.
Indoxazen, 993.
Induline-group, 341.
Indulines, 492.
—— formation of, 1476.
Inositol, thermochemistry of, 764.
Inulin, thermochemistry of, 764.
Invertebrates, blood of, 648.
Iodates, estimation of, in potassium iodide, 657.
Iodic acid and its salts, 1388.
—— —— use of, in quantitative analysis, 1027.
Iodides, estimation of, 527.

Iodine, action of, on potassium chlorate, TRANS., 925.
—— action of, on potassium sulphite and thiosulphate, TRANS., 1083.
—— action of, on sodium hydrogen sulphite, 681.
—— and its oxy-acids, action of, on hydrogen peroxide, 539.
—— bromine and chlorine, exchange of, between inorganic and organic haloïd compounds, 574.
—— —— —— separation of, 1028.
—— chlorine compounds of, 1387.
—— detection of bromine and chlorine in presence of, 1514.
—— fixation of, by starch, 578.
—— free, estimation of, 539.
—— heat of combination of, with magnesium, 762.
—— solubility of, in chloroform, 769.
—— trichloride, 1388.
Iodochromate, 124.
Iodoform, estimation of, 1528.
Iodometry, 1514.
Iolite, composition of, 793.
Ions, colour of the, 1137.
—— electromotive activity of the, 671.
Iridium, removal of platinum from, 1285.
Iron, action of carbonic oxide on, 568.
—— action of chlorine and of bromine on, 118.
—— action of nitric acid on, 1278.
—— action of nitric oxide, on, 1152.
—— action of water gas on, PROC., **1891**, 126.
—— ammonium sulphates, 943.
—— and aluminium, estimation of, by the Glaser method, 755.
—— —— estimation of, in the presence of phosphoric acid, 755.
—— cast, calorimetric researches on the condition of silicon and aluminium in, 19.
—— calorimetric estimation of, 240, 1132.
—— direct estimation of aluminium in, 102.
—— distribution and condition of, in barley, 1509.
—— electrolytic separation of, 917.
—— estimation of carbon in, 913, 1030.
—— estimation of, in aluminium, 1131.
—— estimation of, in phosphates, 536.
—— estimation of manganese in, 916, 1030, 1514.
—— estimation of phosphorus in, 528, 529, 911.
—— estimation of sulphur in, 1376.
—— Hamburger's method for the estimation of small quantities of, 1525.
—— in bone-black, 1053.
Iron, intake of, by the fœtus, 516.
—— in the fœtal organism, 1502.
—— in the liver, 1503.
—— manganese, and calcium, separation of, 916.
—— metallic, estimation of, in *ferrum reductum*, 1524.
—— native, from Cañon Diablo, 947.
—— occlusion of hydrogen by, 567.
—— pig, estimation of phosphorus in, 912.
—— —— estimation of sulphur in, 382.
—— precipitation of copper by, 276.
—— salts, action of alkaline polysulphides on, 537.
—— —— utilisation of burnt pyrites in the preparation of, 1281.
—— separation of, from cobalt, nickel, and manganese, 103.
—— testing, for arsenic, 1030.
—— volumetric estimation of, 240.
—— wrought, estimation of slag in, TRANS., 551.
Iron-ores, estimation of phosphorus in, 529,
—— —— genesis of, by replacement of limestone, 126.
—— —— of Central Russia, 689.
—— —— of the Marquette district, Michigan, 794.
Iron. See also Ferric and Ferrous.
Isaldoxime-derivatives, intramolecular change of, 50.
Isidiomatic compounds, 1366.
Isoamyl alcohol, vapour tension of, 397.
—— iodide, action of, on trimethylamine, 805.
Isoamylaniline, 44.
Isoamylbenzene, 985.
Isoamylene, condensation of, with phenols, 446.
Isoamylguanamine, formation of, 736.
Isoamylparisopropyltoluene, ortho-, 985.
Isoamylthymol, 446.
Isoanemonic acid, 1241.
Isoanemonin, 1241.
Isoanilides, 705.
Isoantipyrine, 635.
Isoapiole, derivatives of, 1315.
—— nitrosite, 447.
Isoapoquinine, 82.
Isoarabic acid, 1180, 1432.
Isobenzaldiphenylmaleïde, 486.
Isobenzaldiphenylmaleïmidine, 486.
Isobutaldehyde, action of zinc and ethyl chlorocetate on, 1300.
—— chlor-, 1292.
Isobutyl alcohol, action of bromine on, 809.

Isobutyl alcohol, action of chlorine on, 1292.
—— —— vapour tension of, 397.
—— iodide, action of, on trimethylamine, 805.
Isobutylallylamine, 31.
Isobutylallylphenylcarbamide, 31.
Isobutylallylphenylthiocarbamide, 31.
Isobutylamine, chloro- and dichloro-, 1172.
Isobutylbenzene (b. p. 165—170°), 44.
Isobutylbenzyl orthoxylyl ketone, 338.
Isobutylbenzylparatolylcarbamide, 1084.
Isobutyldibenzylcarbamide, 1083.
Isobutylisobutylideneamine, 1173.
Isobutylparaditolylcarbamide, 1083.
Isobutylparisopropyltoluene, ortho-, 985.
Isobutylphenylhydrazone, thionyl-, 1324.
Isobutylpheuylthiocarbamide, symmetrical, 702.
Isobutylpropargylamine, 32.
Isobutylpropylamine, 32.
Isobutyric acid, bromo-, action of ammonia on, 1302.
—— diphenylhydrazide, 981.
—— phenylhydrazide, 981.
Isocamphenol, properties of, 199.
Isocamphor, 199.
Isocarbostyril, 882.
Isocarbostyrilcarboxylic acid, 882, 970.
Isocinchonidinesulphonic acid, 514.
Isocinchonine, 222.
Isocinchoninesulphonic acid, 515.
Isoconchininesulphonic acid, 514.
Isocoumarincarboxylic acid, 970.
Isocrotonaldehyde, presence of, in a brandy, 810.
Isocrotonic acid, derivatives of, 295.
—— —— oxidation of, 957.
Isocyanates, aromatic, 832.
Isocyanides, refractive powers of, 757.
Isocyanoparatolyl dichloride, 1442.
Isocyanophenyl dichloride, 1439.
Isocyanorthotolyl chloride, 1441.
Isodehydrocholal, 741.
—— chloro-, 741.
Iso-β-dichlorhydrin metahydroxybenzoate, 471.
Isodihydroxybutyric acid, 958.
Isodihydroxycaproic acid, salts of, 959.
Isodissociation, laws of, 3.
Isoerucic acid, 812.
Isoethenyldiamidotoluene, derivatives of, 838.
Isoeugenol and its derivatives, 45.
Isofenchonoxime, β-, 1237.
Isohexeric acid, 958.
Isohydrotannic acid, 182.
Isohydroxycaprolactone, 959.
Isohyposantonic acid, 870.
Isohyposantonin, 870.
Isomalic acid, 824.
Isomaltose, 1293.
Isomangostin, 206.
Isomerism, special case of, 1067.
Isomethylpæonol, 846.
Isomorphous mixtures, freezing point of, 396.
Isonaphthazarin, 494, 720.
Isonipecotinic acid, 1486.
Isonitroso-compounds, action of sulphurous acid on, 475.
Isoparaxylalphthalide, 474.
Isoparaxylalphthalimidine, 474.
Isophthalamidine nitrite, 53.
Isophthalic acid, asymmetrical amido-1464.
—— —— —— bromo-, 337.
—— —— parachloro-, 1201.
Isoprene, spontaneous conversion of, into caoutchouc, 1482.
Isopropane, nitro-, action of methyl iodide and chloroform on, 1290.
Isopropyl alcohol, action of bromine on, 809.
—— —— and sodium, thermochemistry of, 674.
—— —— properties of, 691.
—— sodium thiosulphate, 1418.
Isopropylacetothienone, β-, 442.
Isopropylbenzene, action of aluminium chloride on, 1309.
Isopropylbenzophenone and its oximes, 489.
Isopropylcoumarin, α-, derivatives of, 330.
Isopropyleneparamidophenol, 1451.
Isopropylmalic acid, 428.
Isopropylphthalimide, 158.
Isopropylpropiothienone, β-, 443.
Isopropylthiocoumarin, 330.
Isopropylthiophen, β-, 442.
—— mercuric chloride, β-, 829.
Isopropyltricarballylic acid, 42.
Isoquinine, 82.
Isoquininesulphonic acid, 514.
Isoquinoline methiodide, oxidation of, 730.
—— preparation of, from naphthalene, 882.
—— pyrogenic synthesis of, 730.
—— sulphonation of, 876.
Isosaccharin, specific rotatory power of, 1421.
Isosafrole, action of nitrous acid on, 1198.
—— action of potash and methyl alcohol on, 972.
—— nitrosite, 447.
—— oxidation of, 310, 328.
—— the oxymethylene group in, 972.
Isosafroledioxime peroxide, 1198.
Isosantinic acid, 872.

Isostrychnic acid, isonitroso-, 1012.
Isosuccinic acid, bromo-, action of alcoholic potash on, 1305.
—— —— thermochemistry of, 1140.
Isosuccinimide, alkyl derivatives of, 701.
Isoterpene from the resin of *Pinus abies*, 625.
Isothermal curves for carbonic anhydride, 3.
Isothermals, change of the empirical and theoretical, of mixtures of two substances with the temperature, 259.
Isovaleric acid, α-bromo-, 427.
Isovaleridenetoluidine, 1194.
Isoxazoles, 506.

Julole-violet, 498.
Julole-violet-base, 499.
Julolidine, 1492.

K.

Kamacite from the Welland meteoric iron, 24
Kamés, relation between truffles and, 654.
Kaolin, estimation of, in arable soils, 1026.
—— from Colorado, 1406.
—— in arable soil, 1026.
Karlsbad salts, analysis of, 659.
Keto-γ_1-benzoxyjuloline, α_1-, 884.
Keto-γ_1-chlorojuloline, α_1-, 884.
Ketodimethyldihydroquinoxaline, 1108.
Keto-β_1-ethyl-γ_1-methyljuloline, α_1-, and its bromo- and nitro-derivatives, 883.
Ketohydroxyhydrindenecarboxylamide, dichloro-, 859.
Keto-γ_1-hydroxyjuloline, α_1-, 884.
Ketomethylbenzyldihydroquinoxaline, 1108.
Ketomethylethyldihydroquinoxaline, 1108.
Keto-γ_1-methyljulolidine, α_1-, 497.
Ketomethyljuloline, dyes obtained from, 498.
—— oxidation and reduction of, 496.
Ketomethylphenyldihydrophenoquinoxaline, 1108.
Ketones, action of paramidodimethylaniline on, 854.
—— action of potassium cyanide on halogen derivatives of, 324.
—— action of sodium on, 169.
—— aromatic alkyl, and their oximes, 985.
Ketones, aromatic, metallic compounds of, 1205.
—— —— nitro-, preparation of, 1459.
—— bromo-, formation of, by the action of bromine on the alcohols of the ethyl series, 809.
—— colour reaction of, with aromatic nitro-compounds, 1263.
—— compounds of, with mercuric chloride, 828.
—— condensation of chloral with, 694.
—— fatty, action of chlorine on, 424, 810.
—— —— mixed, oxidation of, 35.
—— of the quinoline series, 1488.
—— physiological action of, 1506.
—— sodium nitroprusside as a reagent for, 924.
—— unsaturated γ-, action of phenylhydrazine on, 995.
Ketonic acids, oximes of, 327.
Ketonic compounds, magnetic rotation of, Trans., 800.
Ketonic oxygen, estimation of, 546, 1530.
—— —— substitution of the azo-group for, 451.
Keto-β_1-nitroso-γ_1-hydroxyjuloline, α_1-, 884.
Ketophenyl-γ-piperidone, pentachloro-α-, 449.
Ketoquinazolines, new synthesis of, 1495.
Ketoximes, aromatic alkyl, 1200.
—— —— influence of substituting radicles on the configuration of, 487.
—— configuration of, 426.
Ketoximic acids, γ-, configuration of, 1202.
Kidney disease, excretion of nitrogen in, 743, 1504.
Knoxvillite, 1407.
Kuromoji oil, 1480.
Kyaphenine, formation and preparation of, 1183.

L.

Lactic acid, action of the bacillus of malignant œdema on, 91.
—— —— formation of, in the organism, 517, 1112.
—— —— inactive, resolution of, by *Penicillium glaucum*, 297.
—— —— resolution of, into its optically active components, Trans., 754.
Lactocrite, 550.
Lactones, 812, 956.
—— and hydroxy-acids, reciprocal transformations of, 1303.

Lactonic acids, 812, 956.
Lactose, acetyl-derivatives of, 948.
—— optically different modification of, 948.
Lapachic acid, bromo-, Paterno's, Trans., 638.
—— —— constitution of, Trans., 611.
Lapachol, constitution of, Trans., 611.
Lapachone, α-, Trans., 635.
Lapachone, β-, Trans., 626.
—— bromo-, Trans., 638.
Lard, detection of vegetable oils in, 1133.
Lard-oil, iodine number of, by Hubl's method, 664.
Latex of *Ficus carica*, 653.
Lathyrus, analyses of, 522.
Laurel, oil of, 722.
Lauric acid, action of bromine on, 696.
Lautarite, 124.
Lavender, oil of, 868, 1235, 1347.
Lavendol, 868.
Law of Van't Hoff, applicability of Planck's proof to the, 935.
Layers, formation of, in solutions of salts in mixtures of water and organic liquids, 1146.
Lead, action of nitric acid on, 410, 1403.
—— action of nitric oxide on, 1151.
—— and bismuth, separation of, by means of bromine vapour, 540, 549.
—— and silver, separation of, 1522.
—— bromosulphide, 685.
—— chlorosulphide, 685.
—— chromate, 567.
—— —— basic, 567.
—— dioxide, electrical conductivity of, 672.
—— double halogen salts of, 779.
—— electrolytic detection of, 541.
—— estimation of, 539, 1522.
—— hydrogen imidosulphonate, Trans., 970.
—— imidosulphonate, Trans., 969.
—— —— five-eighths oxy-, Trans., 978.
—— —— hemihydroxy-, Trans., 970.
—— lowering of the freezing point of cadmium by, Trans., 903.
—— lowering of the freezing point of, when alloyed with other metals, Trans., 888, 904.
—— magnesium bromide, 566.
—— new oxyiodide of, 1280.
—— nitride, 112.
—— occlusion of hydrogen by, 942.
—— potassium bromide, 779.
—— —— iodide, equilibrium of, with its aqueous solution, 560.
Lead potassium iodides, 779.
—— separation of bismuth from, 385.
—— silver, and zinc, separation of, in galena and blende, 1378.
—— sulphate, analysis of, 1522.
—— —— crystalline, 1399.
—— tin, bismuth, and cadmium, separation of, 754.
—— volumetric estimation of, 1375.
Lead-gold alloy, analysis of, Trans., 912.
Lead-potassium alloy, 773.
Lead-sodium alloy, 773.
Lead-thallium alloy, analyses of, Trans., 914.
Leaves, compounds containing chlorophyll in, 746.
—— etiolated, acquisition of green colour and growth of, 520.
—— —— effect of light on, 521.
—— green and etiolated, amount of proteïds in, 520.
—— of the apple tree, analyses of, 1372.
—— young, absence of oxalates in, 651.
Lecture experiment, burning sulphur in oxygen, 679.
—— —— combination of electrolytic gas, 562.
—— —— diffusion of gases, 562.
—— —— dissociation of phosphonium bromide, 401.
—— —— effusion of gases, 1150.
—— —— occlusion of hydrogen by palladium, 563.
—— —— to illustrate the phenomena of coal dust explosions, Trans., 414.
Leguminosæ, composition of, 521.
—— source of the nitrogen of, 367, 378.
Lemon oil, crystalline products from, 349.
—— —— reaction of, with mercurous salts, 386.
Lemons, Californian, analyses of, 1511.
Lepidone-violet, 499.
—— —— base, 499.
Lettuce, cooked, composition of, Trans., 227.
—— existence of hyoscyamine in, Trans., 90.
Leucæmic patients, peptones in the blood and organs of, 519.
Leucite, artificial reproduction of, 1161.
Leucomaïne, a new, 1367.
Level for gas analysis, 400.
Levulinic acid, action of iodic acid on, 1179.

Levulinic acid, condensation of, with aldehydes, 147.
—— —— condensation of, with furfuraldehyde, 442.
—— —— isonitroso-, 1074.
—— —— magnetic rotation of, TRANS., 800.
—— —— phenylhydrazonehydrazide of, 436.
—— oxime, 1202.
Levulinicphenylhydrazoneazobenzene, 436.
Levulose, cane-sugar, and invert-sugar, examination of, 248.
Licareol, 1236.
Licarcone, 1236.
Licari kanali, essential oil of, 1236.
Light, action of, on oxyhydrogen gas, 939.
—— action of, on ruthenium peroxide, 282.
—— action of, on silver chloride, 775; TRANS., 728.
—— effect of, on etiolated leaves, 521.
Light-intensity, measurement of, 253.
Lignin, 802.
Lignite tar, 1075.
Lignocellulose, reaction of, with ferric ferricyanide, 1421.
Lignocelluloses, 693.
—— constitution of, 129.
Lime, action of, as a manure, with especial regard to paddy fields, 93.
—— action of, on heavy loams, 523.
Lime-seed, oil of, 92.
Limettin, TRANS., 344.
—— action of hydrating agents on, TRANS., 351.
—— action of hydriodic acid on, TRANS., 350.
—— dibromo-, TRANS., 348.
—— nitro-, TRANS., 350.
—— oxidation of, TRANS., 346, 349.
—— trichloro-, TRANS., 349.
Limonene nitrosochlorides, 1349.
Limonenenitrolanilide, hydrochloro-, 1349.
Limonenenitrolanilides, 1348.
—— nitroso-, 1348.
Limonenenitrolbenzylamine, hydrochloro, 1349.
Limonene-series, isomerism in the, 1348.
Limonite in Texas, 1405.
Linaloöl, 868, 1347.
Linamarin, 502.
Lindera sericea, oil of, 1480.
Linseed, sugar from, 1293.
Liquids, application of capillary phenomena to the analysis of, 236.
—— calculation of the specific heat of, 2.
Liquids, heat of dissolution of gases in, 1042.
—— mixed, critical temperatures of, 262.
—— molecular weights of, as evinced by their boiling points, 107.
—— organic, as solvents for metallic salts, 558.
—— relations between compressibility and indices of refraction of, 669.
—— specific heat of, at temperatures above the boiling point, 761.
—— temperatures of saturated vapours of various, under the same pressure, 1143.
—— viscosity of, 1143.
Lithium bromate, 1275.
—— chloride, boiling points of solutions of, TRANS., 341.
—— copper chloride, 118.
—— double chlorides of, with metals of the magnesium group, 1275.
—— hypophosphate, 403.
—— nitride, 565.
—— stannibromide, 121.
Liver, horse's, cystin and xanthine in the, 516.
—— iron in the, 1503.
Live-weight, influence of various salts on, 647.
Loam, heavy, fertility of, increased by lime, 523.
Lotus corniculatus and *L. uliginosus*, composition of, 522.
Lubricating oils, rapid determination of the composition of, 665.
Luminosity of coal-gas flames, TRANS., 322.
Lungs, influence of oxygen on the separation of carbonic anhydride in the, 1369.
Lupanine, the alkaloïd of the blue lupine, 223.
Lupeose, 1171.
Lupins, yellow, assimilation of free nitrogen by, 371, 372, 374.
Lupinus albus, alkaloïds of, 892.
Luteocobalt diaminechromium thiocyanate, 1001.
Lutidine, 2 : 6-, action of benzaldehyde on, 1360.
Lutidinic acid, 75.
Lycium barbarum, alkaloïds of, 232.
Lycopodium saururus, alkaloïds from, 894.
Lysine, 1500.

M.

Magdala-red, solutions of, TRANS., 160, 163.

Magnesium acetate, action of magnesium oxide and lead oxide on, 1178.
—— action of chlorine and of bromine on, 118.
—— action of hydrogen peroxide and of water saturated with carbonic anhydride on, 17.
—— action of nitric acid on, 1403.
—— action of, on ammonia, 409.
—— action of, on chlorides, 776.
—— chloride, boiling points of solutions of, TRANS., 341.
—— estimation of, in guncotton, 1520.
—— heats of combination of bromine and iodine with, 762.
—— hypophosphate, 404.
—— lead bromide, 566.
—— lowering of the freezing point of lead by, TRANS., 904.
—— manganese chloride and bromide, 781.
—— nitride, 409.
—— orthoborate, 404.
—— oxide, action of hydrogen peroxide on, 1278.
—— permolybdate, 1160.
—— stannibromide, 121.
Magnetic rotation of compounds supposed to contain acetyl, or to be of ketonic origin, TRANS., 800.
—— —— of dissolved salts, PROC., **1892**, 12.
Magnetism and atomic weight, 672.
—— of organic compounds, 672.
Maize, proteïds of, 379, 746, 749.
Maize-fibrin, 749.
Mäize-myosin, 747.
Maize-vitellin, 747.
Maleïc acid, complete transformation of fumaric acid into, 1306.
—— —— thermochemistry of, 1041.
—— —— transformation of, into fumaric acid, 297, 1305.
—— anhydride, preparation of, 963.
Malic acid, new synthesis of, 429.
—— —— separation of, from citric, succinic, and tartaric acids, 1531.
—— —— thermochemistry of, 260.
—— diphenylhydrazine, action of carbonyl chloride on, 511.
Malonamide, diamido-, 40.
—— imido-, 40.
Malondianilide, 1072.
Malonic acid, dibromo-, 1140.
—— —— halogen derivatives of, 39.
Maltose, action of alkaline mercuric cyanide on, 1032.
—— estimation of, in beer and beer wort, 248.
—— hydrate, disappearance of the multirotation of, in ammoniacal solution, 1419.
Maltose, thermochemistry of, 764.
Mammals, formation of uric acid in the blood of, 1257.
Mandelamide, 1203.
Mandelic acid and its nitrile, 1088.
—— —— preparation of the amide, anilide, and phenylhydrazide of, 473.
Mandelic-ψ-tropeïne, 891.
Manganese, action of carbonic oxide on, 568.
—— action of nitric acid on, 1403.
—— and zinc, separation of, 384.
—— calcium, and iron, separation of, 916.
—— compounds, 1052.
—— double halogen salts of, 780.
—— estimation of, by the chlorate method, 1132.
—— estimation of, in iron and steel, 816, 1030, 1524.
—— estimation of, in its ores and alloys, 536.
—— estimation of, in slags and ores, 385.
—— hydroxide from the Euganeen, Italy, 689.
—— separation of iron from, 103.
—— separation of nickel and cobalt from, 240.
—— separation of zinc from, 537.
—— sodium metaphosphate, 1053.
—— tetrachloride, 19.
—— —— hypothetical, 687.
Manganese-ores, estimation of cobalt in, 917.
Manganese-spar from Arzberg, 1406.
—— from Scharfenberg, 1406.
Manganic hydrogen pyrophosphate, 1052.
—— potassium pyrophosphate, 1052.
Manganophyll from Harstigen Mine, Sweden, 1411.
Manganous oxide, action of nitric oxide on, 1152.
—— chloride, 780.
Mangostin, 205.
Mannitol, a pure fermentation of, TRANS., 254.
—— and boric acid, freezing points of aqueous solutions of, 263.
—— fermentation of, with *Bacillus ethaceticus*, TRANS., 432.
—— monosodium, 800.
—— nitrate, action of alkaline solutions on, 692.
—— occurrence of, in the fruit of the cherry laurel, 908.
—— thermochemistry of, 764.
Mannose, detection of, in vegetable products, 250.
Manure, action of lime as a, with especial regard to paddy fields, 93.

Manure, farmyard, fermentations of, 1123.
—— value of animal *débris* as nitrogenous, 96.
Manures, nitrogenous, preservatives for, 378.
Margarin, detection of, in butter, 1034.
—— estimation of fat in, 392.
Martite from Brazil, 1055.
Masrite, TRANS., 494.
Masrium, TRANS., 494.
Meat, raw and boiled, digestibility of, 1367.
Mechanical theory of heat, recent developments of, 395.
Medicago, analyses of different species of, 522.
Medicagol, 746.
Meionite, Vesuvian, formula of, 417.
Meldometer, 414.
Melicitose, thermochemistry of, 764.
Melilite, composition of, 1410.
—— formation of, during the burning of Portland cement, 416.
Melilite-bearing rock from Canada, 1058.
Melilotus alba and *M. officinalis*, composition of, 522.
Melitose, thermochemistry of, 764.
Melting point, depression of, by phenol, 556.
—— —— of minerals, determination of, 414.
Melting points of mixtures, 1139.
Membranes, precipitated, permeability of, 1383.
Menthene, 866, 1479.
—— constitution of, 624.
—— nitrosochloride, 1479.
—— preparation of, 623.
Menthodicarboxylic acid, 202.
Menthol and its derivatives, 866.
—— constitution of, 624, 625.
—— conversion of, into cymene, 200.
Menthonaphthene, 866.
Menthone and its derivatives, 867.
Menthyl ethyl ether, 200, 348.
Menthylamine, 500, 723.
Menyanthes trifoliata, constituents of, 1262.
Menyanthin, 1262.
Menyanthol, 1262.
Mercapturic acids, oxidation products of, 1090.
Mercurammonium compounds, 276.
Mercuric cadmium cyanide, TRANS., 687.
—— chloride, boiling points of solutions of, TRANS., 340.
—— —— solubility of, in various organic liquids, 558.
—— cyanide, action of aluminium and of nickel, &c., on, dissolved in water and in organic solvents, 797.
Mercuric cyanide, action of ammonia on, 575.
—— —— boiling points of solutions of, TRANS., 340.
—— disodium imidosulphonate, TRANS., 980.
—— fulminate, action of chlorine on, 26.
—— —— constitution of, 25.
—— thiocyanate, double salts of, with other thiocyanates, 10.
—— zinc cyanide, TRANS., 666.
Mercurioanilido-compounds, 1448.
Mercuriophenylamine, 1448.
Mercurosammonium compounds, so-called, 685.
Mercurous hypochlorosulphite, 780.
—— nitride, 112.
—— oxide, action of sulphur on, 770.
—— permolybdate, 1160.
—— salts, action of ammonia on, 686.
—— —— action of hydrogen cyanide on, 1416.
Mercury, action of nitric acid on, 1403.
—— adhesion of, to glass in presence of halogens, TRANS., 452.
—— compounds of acetylene, PROC, **1892**, 110.
—— dihydrogen imidosulphonate, TRANS., 977.
—— electrolytic separation of, 239, 541, 920.
—— electrolytic separation of, from copper, 239.
—— electrolytic separation of, from osmium, 920.
—— hydrosulphides, TRANS., 123.
—— imidosulphonates, TRANS., 976.
—— —— constitution of, TRANS., 985.
—— lowering of the freezing point of bismuth by, TRANS., 897.
—— lowering of the freezing point of cadmium by, TRANS., 903.
—— lowering of the freezing point of lead by, TRANS., 910.
—— phosphide, 1398.
—— potassium imidosulphonate, TRANS. 976.
—— separation of, from arsenic, phosphoric, and nitric acids, and from chlorine and sodium, 530.
—— sodium imidosulphonates, TRANS., 980.
—— sulphide, colloïdal solutions of, TRANS., 138.
—— volumetric estimation of, 663; TRANS., 364.
Mesaconic acid, conversion of, into its isomerides by soda, 297.
Mesitylene, derivatives of, 329.
—— fluoro-, 968.
—— iodo-, 967.
Mesitylglycollic acid, 329.

Mesitylglycollic chloralide, 329.
Mesitylglyoxylic acid, salts of, 329.
Mesoxaldehyde, symmetrical bisphenylhydrazone of, 162.
Mesoxanilide, 1439.
—— alcoholate, 1439.
—— hydrate, 1440.
—— imidochloride, 1439.
Mesoxanilidephenylhydrazone, 1439.
Mesoxatoluidide hydrate, 1442.
Metabolism of pigs fed on corn cockle, 1018.
Metallic chlorides, action of magnesium on, 777.
—— films, colours and absorption spectra of, 1037.
—— oxides, action of sulphur and water on, 770.
Metals, action of nitric oxide on, 1151, 1390.
—— action of, on salts dissolved in organic liquids, 797.
—— and nitric acid, reaction between, 1402.
—— direct combination of chlorine with, 118, 401.
—— direct combination of chlorine and bromine with, 118.
—— electrical behaviour of, in salt solutions, 393.
—— electrical volatility of, 1037.
—— electrolytic estimation of, 1521.
—— electrolytic estimation of, as amalgams, 753.
—— heavy, volumetric estimation of, 1521.
—— nitro-, 1390.
—— transportation of solids in a vacuum by the vapours of, 1386.
Metapectic acid, 291.
Metaphosphates, 1045.
Meteoric iron, discovery of diamonds in, 284.
—— —— from Colfax Township, North Carolina, 1059.
—— —— from Maryland, 794.
—— —— Welland, kamacite, tænite, and plessite from, 24.
Meteorite from Kansas, 795.
—— of Jelica, 795.
—— of Ljungby, 1060.
—— of Misshof, in Kurland, Russia, 1059.
—— the Tonganoxie, 284.
Meteorites from Atacama, Chili, 1413.
—— new, 1413.
—— of Turgaisk, 418.
Methane, absorption coefficient of, in water and in alcohol, 1044.
—— action of heat on, Trans., 328.
—— flame, experiments on, Trans., 310.
Methane, iodonitro-, preparation of, 1415.
Methaneazobenzene, iodonitro-, 1416.
Methaneazotoluene, iodonitro-, 1416.
Methenylamidoximeacethydroxamic acid, 139.
Methenylnaphthaleneamidine, 1496.
Methoxyacetophenone, ortho-, 845.
Methoxyacetophenonecarboxylic acid, 1231.
Methoxybenzhydrylamine, para-, 338.
Methoxybenzophenone, para-, chloride, 339.
—— —— hydrazones of, 340, 598.
Methoxybenzophenone-β-naphthylamine, para-, 339.
Methoxybenzophenoneparamidobenzoic acid, para-, 340.
Methoxybenzophenoneparatoluidine, para-, 339.
Methoxybenzoylacetic acid, ortho-, 844.
Methoxybenzylideneorthamidophenol, 1451.
Methoxybenzylideneparamidophenol, 1451.
Methoxycresol, 447.
Methoxydiazobenzenesulphonic acid, para-, 1081.
Methoxyethylbenzoic acid, orthochloronitro-, 1231.
Methoxyjulolidine, para-, 1492.
Methoxyorthohydroxyacetophenone, para-, 59.
Methoxyquinine methiodide, 1363.
Methoxyparahydroxybenzophenylhydrazone, ortho-, 317.
Methoxyphenyldimethylpyrazolone, para-, 1082.
Methoxyphenylhydrazine, para-, 1082.
Methoxyphenylhydrazinesulphonic acid, salts of, 1081.
Methoxyphenyloximidoacetic acid, para-, 328.
Methoxyphenylphenylpyrazolone, ortho-, 844.
Methoxypyridine, α-, 209.
Methyl acetoneoxalate, magnetic rotation of, Trans., 822, 853.
—— acetophenoneoxalate, magnetic rotation of, Trans., 833, 863.
—— alcohol, vapour tension of, 397.
—— alloethyl camphorate, ortho-, 1102.
—— α-amidopropionate hydrochloride, 453.
—— apionylglyoxylate, 328.
—— azomethylenecarboxylate, 452.
—— benzeneazocamphocarboxylate, 1344.
—— benzenesulphonate, 1220.
—— bromobenzenesulphonate (para-), 1220.
—— bromotetramethylenecarboxylate, Trans., 43.

Methyl butyl ether, 27.
—— —— ketone, oxidation of, 36.
—— camphocarboxylates, 1342.
—— camphorate, 1346.
—— carboxymethylacetoacetate, 1070.
—— chlorobenzenesulphonate (para-), 1220.
—— cumaroketone (ortho-), 169.
—— α-diazopropionate, 452.
—— dicarboxyglutarate, 1040.
—— —— thermochemistry of, 1041.
—— dioxymethylenephenylglyoxylate, 327.
—— dioxymethylenephenyloximidoacetate, 327.
—— diphenyl tricyanide, formation of, 1184.
—— ethyl ketone, action of chlorine on, 425.
—— —— ketoxime, action of phosphoric chloride on, 426.
—— —— sulphide, preparation of, 1422.
—— hexyl ketone, isonitroso-, 971.
—— —— —— normal, 293.
—— —— ketoxime, 427.
—— hydrogen camphorate, 1346.
—— —— —— allo-, Trans., 1093.
—— —— —— —— crystallography of, Trans., 1094.
—— —— —— ortho-, 1102 ; Trans., 1088.
—— —— —— —— crystallography of, Trans., 1088.
—— —— camphorates, action of phenylcarbimide on, 1347.
—— —— phthalate, dissociation constant of, Trans., 717.
—— —— —— preparation of, 1204.
—— —— succinate, dissociation constant of, Trans., 716.
—— hydroxycinnamyl ketone (ortho-) and its derivatives, 169.
—— α-hydroxypropionate, nitro-derivatives of, 583.
—— imidomethylphenylthiocarbamate, 466.
—— imidophenylthiocarbamate, 465.
—— isoamyl ketone, oxidation of, 36.
—— isobutyl ketone, 36.
—— isopropyl ketoxime, action of phosphoric chloride on, 427.
—— licaryl ether, 1236.
—— mesitylenecarboxylate, 329, 715.
—— methylcamphocarboxylate, 1344.
—— methylimidomethylphenylthiocarbamate, 466.
—— methylphenyldithiocarbamate, 466.
—— methylphenylthiocarbamate, 466.
—— morphine carbonate, 638.
—— α-naphthalenesulphonate, 1220.
—— β-naphthalenesulphonate, 1220.
Methyl naphthyl ketones, action of phosphoric chloride on, 465.
—— β-naphthylsulphinate, 623.
—— naphthylsulphoneformate, 623.
—— opianates, normal and pseudo-, 1209.
—— phenylamidoacetate, 468.
—— phenylcarbamate, nitration of, 711.
—— phenylimidomethylphenylthiocarbamate, 466.
—— phenylmethyltriazolecarboxylate, 638.
—— propyl ether, 27.
—— —— ketone, hepatchloro-, 1463.
—— —— —— hexachloro-, 1462.
—— α-pyridyllactate, 76.
—— salts of abnormal structure, 1208.
—— tetrachloro-α-hydroxyhydrindenecarboxylate, 858.
—— tetrahydroquinolinecarboxylate, 355.
—— trimethylenetetracarboxylate (1 : 1 : 2 : 2-), 1040.
Methylacetylacetone, magnetic rotation of, Trans., 813, 842, 848.
—— refractive and dispersive powers of, Trans., 850, 852.
Methylacetylacetonitrile, 810.
Methylacetylcarbinol, 810.
Methylacetylcarbinyl acetate and butyrate, 810.
Methyl-β-acetylquinoline, α-, 1107.
Methylacridone, 881.
Methylalloxazine, 70.
Methylamidocrotonanilide, 965.
Methylamidocrotonanilide, β-, 708, 1106.
Methylamidoparadiketohexene, pentachloro-, 449.
Methylamine hydrogen diaminechromium thiocyanate, 1000.
—— —— malate, action of heat on, 820.
—— platinothiocyanate, 286.
Methylarecaïdine, 739.
Methylbenzenes, condensation of, with allyl alcohol, 156.
Methylbenzylamine, 65.
Methylbenzylmetaxylidine, 1320.
Methylbenzylorthotoluidine, 313.
Methyl-μ-benzyloxazoline, β-, 214.
Methylbergaptic acid, 71.
Methylbromophenyldibromopyrazolone, 1246.
Methylcamphor, 1343.
Methylcarbazacridine, 343.
Methylchlorostilbene, 1224.
Methyl-μ-cinnamenyloxazoline, β-, 215.
Methylcoumaroxime, α-, 330.
Methylcrotonanilide, β-, derivatives of, 1106.
Methyldeoxybenzoïnorthocarboxylic acid, para-, 473.
Methyldeoxystrychnine, 1014.

Methyldiphenylformamidine, 707.
Methyldipyridyls, 75.
Methyldithiobiuret, α-, 703.
Methylene iodide, action of, on diethyl malonate, 1304.
—— —— action of silver nitrite on, 1415.
—— —— refractive power of, at different temperatures, TRANS., 296.
—— iodo-, reaction of, with silver nitrate, 575.
Methylenecarbazole, 1466.
Methylenecinchonic acid, 1489.
Methylenecinchoxinic acid, 1490.
Methylenediacetamide, 579.
Methylenedibenzamide, 467, 580.
Methylenedigallic acid, 856.
Methylene-3 : 4-dihydroxybenzyl glycol, 47, 310.
Methylenedimetanitraniline, 1450.
Methylenediditrodibenzamide, 467.
Methylenediorthonitraniline, 1450.
Methylenediorthotoluylamide, 467.
Methylenediparanitraniline, 1450.
Methylenediparatoluylamide, 467.
Methylenedipyrogallol, 856.
Methylenediresorcinol, 856.
Methylenediresorcylic acid, 856.
Methylenedisalicylic acid, 855.
—— —— condensation of, with β-resorcylic acid, with gallic acid, and with phenol, 857.
Methylenedithioacetamide, 580.
Methylenedi-α-toluylamide, 467.
Methylenehydroxyquinolinium, 878.
Methylenephthalyl, nitro-, 1231.
Methylethylacraldehyde, action of sulphuric acid on, 951.
Methylethylbenzene, metadiamidopara-, 606.
Methylethylbromazolone, 79.
Methylethylhydroxyquinoline, 79.
Methylethylisoxazole, amido-, 79.
Methylethylpiperidylalkine [2 : 5-], 1358.
Methylethylpyridylalkine [2 : 5-], derivatives of, 1358.
Methylethylsulphine, preparation of, 1522.
Methyleugenol, glycol from, 310.
Methylfenchylamine, 1239.
Methylfumaramic acid, 821.
Methylfumarimide, 821.
Methylfurfurylthiocarbamide, 43.
Methylglutaric acid, β-, 41.
Methylglyoxaline, action of ethyl chloracetate on, 1493.
Methylglyoximecarboxylic acids, dissociation constants of, 1268.
Methylguvacine, 740.
Methylhexahydronicotinic acid, 740.
Methylhexylcarbin cyanide, 132.
Methylhexylethylene, β-, 132.
Methylhydantoïn, γ-, 828.
Methylhydratropic acid, para-, 605.
—— —— —— metadiamido-, 606.
—— —— —— metadinitro-, 606.
Methylhydrazimethylenecarboxylic acid, ammonium salt of, 452.
Methylhydrindone, ortho-, 1221.
—— —— phenylhydrazone, 1221.
Methylhydrobergaptic acid, 72.
Methylhydrocinnamic acid, ortho-, 1221.
—— acids, condensation of, to the corresponding methylhydrindones, 1221.
Methylhydrocotoïn, action of phosphoric chloride on, 1314.
Methylhydrohydrastinine, bromo-, 223.
Methylhydroxy-γ-acetoxime-δ-isonitrosoamidovaleric acid, β-, lactam of, 326.
Methylhydroxy-γ-cyanacetobutyronitrile, β-, 325.
Methylhydroxylamine, 1067.
Methylhydroxyphthalanil, α-, 608.
Methylhydroxyphthalanilic acid, α-, 608.
Methylhydroxypyrimidinecarboxylic acid, 1008.
Methylhydroxytoluquinoxaline, 1359.
Methylindole, α-, action of methyl iodide on, 614.
Methylisobutylthiocarbamide, symmetrical, 702.
Methylisoeugenol, glycol from, 311.
—— nitrosite of, 447.
Methylisoform-α-naphthalide, 705.
Methylisoformoparatoluidide, 708.
Methylisoformorthotoluidide, 707.
Methylisoglyceric acid, β-, 296.
Methylisoglycidic acid, β-, 296.
Methylisoxazole, α-, 1073.
Methylisoxazole, γ-, 1073.
Methyljulolidine, γ_1-, 498.
Methyllepidone, dyes obtained from, 498.
Methylmalic acid, β-, 589, 963.
Methylmalonic acid, thermochemistry of, 1140.
Methylmetanitroformanilide, 706.
Methylmetanitroisoformanilide, 706.
Methyl-μ-metanitrophenyloxazoline, β-, 214.
Methylmethenylnaphthaleneamidine, 1496.
Methylnaphthalene, α-, chloro-, 494.
—— nitro-, 494.
—— trichloro-, 493.
Methylnaphthalene, β-, chloro-, 494.
—— chloro-derivatives of, 493.
Methylnaphthalenes, α- and β-, 492.
—— action of chlorine and of nitric acid on, 493.
Methylnaphthaloxazine, 70.
Methyl-α-naphthindole, 3′-, 1479.

Methylnonylacetylene, 1164.
Methylœnanthaldoxime, 1436.
Methylorthocumaryl alcohol, 169.
Methylorthophenylenediamine, 1475.
Methyloxymethylenetribromopyrogallol, 311.
Methyl-α-oxy-β-methylhydroquinoxaline, meta-, 1359.
Methylparaphenylglycoluric acid, 828.
Methylparethyltoluene, meta-, 985.
Methylpentadecylacetylene, 1163.
Methylphenanthridine, ortho- 198.
Methylphenanthridine, para-, 197.
Methylphenanthroline, 729.
Methylphenyldihydroquinazoline, 81.
Methylphenyldihydroxyglutaric acid, 1471.
Methylphenylenethenylamidine, 1475.
Methylphenylhydrazone, thionyl-, 1324.
Methyl-2′-phenylindole, 1-, 1465.
Methyl-2′-phenylindole, 3-, 1466.
Methylphenylketodihydroquinazoline, 81.
Methylphenylpyrazolone and its derivatives, 1245.
Methylphenylpyrazolonesulphonic acid, 1245.
—— chloride, dichloro-, 1246.
Methylphenyltetrahydroquinazoline, 81.
Methylphthalic acid, 1221.
—— —— α-, 607.
—— anhydride, 1221.
Methylphthalide, dichloronitro-, 1231.
Methylphthalimide, 1221.
—— α-, 607.
Methylphthalodiamide, α-, 607.
Methylpipecolylalkine, 1-, 1245.
Methylpiperidine, β-, derivatives of, 629.
Methylpropylacetic acid, preparation of, from ethyl acetoacetate and from diethyl malonate, 581.
—— —— solubility of salts of, 581.
Methylpropylketoxime, action of phosphoric chloride on, 427.
Methylprotocotoïn, 63.
—— action of phosphoric chloride on, 1314.
Methyl-α-pyridone, 209.
Methyl-γ-pyridone, αββ-trichloro-, 450.
Methyl-γ-pyridonecarboxylic acid, αββ-trichloro-, 450.
Methylpyrrodiazole, 636.
Methylquinidine, 1250.
Methylquinine, preparation of, 222.
Methylquinoline, amidochloro-, 728.
—— quinone oximes, 727, 728, 729.
Methylquinolines, amido-, 727, 728.
—— derivatives of, 726.
—— nitro-, 727, 728.
Methylquinolone, bromo- and nitro-derivatives of, 879, 880, 881.
Methylsaccharin, 1092.
Methylstrychnic acid, 1012.
Methylsuccinic acid, thermochemistry of, 1140.
Methylsulphonecorthamidobenzamide, 335.
Methylsynglyoximecarboxylic acid, 1176.
Methylsynketoximepropionic acid, 1202.
Methyl-Δ²-tetrahydro-2-hydroxyethylpyridine, 1-, 1244.
Methyltetrahydroketoquinoxaline, 887.
Methyltetrahydroketotoluquinoxaline, 887.
Methyltetrahydronicotinic acid, 740.
Methyl-Δ²-tetrahydropicoline, 1-, 1243.
Methylthiobiuret, α-, 703.
Methylthiocarbamide, polymeric, 798.
Methylthiocarbimide, compound of, with aldehyde-ammonia, TRANS., 517.
Methylthiocoumarin, α-, 329.
Methylthiohydantoïn, 151.
Methylthiophen, dibromo-β-, 830.
—— mercuric chloride, α-, 829.
Methylthiophen-α-carboxylic acid, β-, 830.
Methylthiophensynaldoxime, 1435.
Methyltolualloxazine, 70.
Methyltribromothiophens, oxidation of, 302.
Methyltricarballylic acid, α-, 41.
Methyltricarballylic acid, β-, 42.
Methyltridecylacetylene, 1163.
Methyltrihydroxybenzophenone, 1225.
Methyltropidine, α-, 358.
Methyltropidine, β-, 359.
Methylumbelliferone, derivatives of, 330.
Methylundecylacetylene, 1164.
Methylxanthone, 1092.
Mica, action of water on, 573.
Micas, constitution of, 125.
Microscopic objects, influence of the composition of the glass of slides and cover glasses on the durability of, 1276.
Milarite, 1056.
Milk, action of pilocarpine on the excretion of, 365.
—— analysis, 517.
—— analysis, the Werner-Schmid method of, 390.
—— cause of the rapid curdling of, during thunderstorms, 1370.
—— estimation of fat in, 549, 550, 1134, 1532.
—— estimation of fat in the products from, 391.

Milk, human, analyses of, 517.
—— is alcohol eliminated by the? 365.
—— putrefaction of, 1116.
Milk-solids, extraction of fat from, 391.
Milk-sterilising apparatus, improvements in Soxhlet's, 518.
Mineral springs of Edepsos, 418.
Mineral water. See Water.
Mineralising influence of ammonium sulphate, 1399.
Minerals, determination of the melting point of, 414.
—— from the chrome iron ore deposits of Maryland, 1057.
—— natural classification of, 415.
Mixtures, liquid and gaseous, volumes of, 935.
—— melting points of, 1139.
Molasses, analysis of, 388.
—— preparation of raffinose from, 422.
Molecular compounds, behaviour of, on dissolution, 1154.
—— dissymmetry, 399, 758.
—— volumes of dissolved substances, 1383.
—— weight, diathermanous power, refractive index, and density of a substance, relation between, 1.
—— weights of liquids, as evinced by their boiling points, 107.
—— —— of substances in solution, modification of Beckmann's boiling point, method of determining, Trans., 989.
Molecules, organic, stereochemical models of, 679.
Molybdenite, analysis of, 657.
Molybdenum, action of nitric acid on, 1403.
—— electrolytic separation of gold from, 920.
—— estimation of, 917.
—— fluoroxy-compounds of, 784.
—— sesquioxide, action of nitric oxide on, 1152.
Molybdic acid, action of hydrogen peroxide on, 944.
—— —— colloïdal solutions of, Trans., 155.
—— —— compounds of sorbitol and perseïtol with, 422.
—— —— estimation of, 241.
Moments of inertia, establishment of fundamental formulæ for the calculation of, 948.
Monchiquite, a rock of the elæolite-syenite class, 1058.
Morphine, hydrogen diaminechromium thiocyanate, 1001.
Morphine-violet, 361.
Mucic acid, action of hydrogen phosphide on, 875.
—— —— lactone, reduction of, 825.
—— —— reduction of, 824.
Mucin in myxœdema, 1117.
Multirotation, disappearance of the, of sugars in ammoniacal solution, 1419.
Muscle, frog, Nasse's experiments on the excitability of, in salt solutions, 515.
Muscular work, influence of, on the elimination of creatinine, 364.
Mushrooms, cooked, composition of, Trans., 227.
Mustard oil, estimation of, 1035.
Myristic acid, 311.
—— —— action of bromine on, 696.
—— —— presence of, in ox gall, 1114, 1503.
Myristicinaldehyde, 311.
Myristin and its derivatives, 311.
Mytilus edulis, blood of, 648.
Myxœdema, mucin in, 1117.

N.

Napelline, Trans., 391.
Naphthachloroquinaldine, β-. 1488.
Naphthadihydroxyquinoxaline, 70.
Naphthalaldehydic acid, 864.
Naphthalene, α- and β-bromo-, action of bromine on, Proc., **1891**, 184.
—— chlorobromonitro- [1 : 4 : 2], Trans., 768.
—— constitution of, 69.
—— αβ-diamido-, action of formaldehyde on, 1496.
—— dibromonitro- [1 : 4 : 2], Trans., 769.
—— homonucleal, tri-derivatives of, Trans., 765.
—— α-nitro-, reduction of, 595.
—— nitrobromiodo- [2 : 4 : 1], Trans., 767.
Naphthalenedicarboxylic acid [1 : 2], 1477.
—— —— dioximimide of, 1477.
—— anhydride [1 : 2], 1477.
Naphthalenes, dibromo-, isomeric, the sulphochlorides of, Proc., **1891**, 182.
Naphthalene-series, products of the reduction of alkylated azo-colours of the, 862.
Napthalenesulphonic acid, 1 : 2-amido-, 345.
—— —— 1 : 2 : 2′-α-amidochloro-, 1479.
—— —— 1 : 2′-α-chloro-, 1478.
—— —— 2 : 2′-chloro-, 1478.
—— —— 2 : 4′-β-chloro-, 1478.
—— —— 1 : 3′ : 4-dichloro-, 344.

Naphthalenesulphonic acid, 1 : 2 : 2′-α-nitrochloro-, 1478.
Naphthalenesulphonic acids, chloro-, 1477.
—— —— dibromo-, preparation of ethereal salts of, PROC., **1891**, 184.
Naphthalenesulphonic chloride, α-, 1220.
Naphthalenesulphonic chloride, β-, 1220.
Naphthalide, oxy-, 864.
Naphthaquinone-, β-, action of hypochlorous acid on, 494, 857.
—— nitro-, action of chlorine on, 1229, 1232.
—— sulphonic acids of, 196.
Naphthaphenoquinoxazine, 887.
Naphthaquinone-α-sulphonic acid, β-, sodium salt of, 196.
Naphthenes and their derivatives, 1182, 1311.
—— and polymethylenes, 1310.
Naphthimidine, 983.
Naphthoethylenediamine, β-, 1248.
Naphthoic acid, trichloro-, 493.
Naphthol, α-, 2-amido-, 861.
—— 4-amido-, 861.
—— —— sulphonic acid from, 721.
—— ethyl ether, 4-amido-, 862.
—— 2-nitro-, 861.
—— 2′-nitro-, 1229.
Naphthol, β-, amido-, 862.
—— 1′-amido-, 122, 1234.
—— 4′-amido-, 1233.
—— benzoyl derivative of, 447.
—— chloro-2′-nitro-, 1229.
—— 1′-nitro-, 1234.
—— 2′-nitro-, 1229.
—— 4′-nitro-, 1233.
Naphtholcarboxylic acid, β-, action of aniline on, 1476.
Naphtholdisazobenzeneorthotoluene, α-, 977.
Naphthols, amido-, homonucleal, 861.
—— nitro-β-, 1341.
Naphthol-α-sulphonic acid, α-, 194.
—— —— β-nitroso-, α-, 195.
Naphtholsulphonic acid, 1.4-amido-, 721.
—— —— [1 : 2-], 345.
—— —— β-amido-α-, 477.
Naphtholsulphonic acid, α-amido-β-, 476.
Naphthol-α-sulphonic acid, β-, calcium salt of, physiological action of, 1116.
Naphtholsulphonic acids, amido-, 996.
—— —— nitroso-, 346.
Naphtho-xanthones, 1100.
Naphthoylacetamide, 983.
Naphthyl ethyl ether, 1 : 4-amido-, and its derivatives, 1097.
—— orthotolylcarbamate, 832.
Naphthylacetylene, α-, and its derivatives, 495.
Naphthylacetylene, β-, and its derivatives, 496.
Naphthylamidobiazolone, α-, 510.
Naphthylamidobiazolone, β-, 508.
Naphthylamidosuccinic acid, α-, 860.
Naphthylamidosuccinic acid, β-, 860.
Naphthylamidosuccinic dinaphthylamide, 860.
Naphthylamidothiobiazolone, α-, 511.
Naphthylamidothiobiazolone, β-, 508.
Naphthylamido-ψ-thiobiazolone, α-, 510.
Naphthylamine, bromo- (m. p. 62°), nonexistence of, TRANS., 766.
—— platinothiocyanates, 287.
Naphthylamine, α-, refractive power of, at different temperatures, TRANS., 303.
Naphthylamine, β-, 4 : 1-bromiodo-, TRANS., 767.
—— 1 : 4-chlorobromo-, 768.
—— nitration of, 1232.
—— 2 : 4′-nitro-, 1233.
—— 2 : 1′-nitro-, 1234.
Naphthylamines, α- and β-, action of, on ethyl bromosuccinate, 860.
Naphthylanilidodithiobiazolone, α-, 511.
Naphthylanilidothiobiazolone, α-, 511.
Naphthylanilidothiobiazolone, β-, 508.
Naphthylaspartic acid, α-, 860.
Naphthyldimethylhydroxypyrimidine, 1009.
Naphthylene dihydrosulphides, 1471.
—— dithiocyanate, 1471.
Naphthyleneamidinedimethoxybenzenylorthocarboxylic acid, αβ-, 1249.
Naphthylenediamine, 2 : 1′-, 1234.
Naphthylenediamine, 2 : 4′-, 1233.
Naphthylenedimethoxyphthalamidone, αβ-, 1249.
Naphthylethylene, chlor-α-, 495.
Naphthylethylene, chlor-β-, 495.
Naphthylglycocinenaphthylide, α-, 1341.
Naphthylglycocine-α-naphthylidoacetic acid, α-, 1341.
Naphthylglycocines, derivatives of, 1341.
Naphthylhydrazone, thionyl-α-, 1324.
Naphthylhydroxypyrimidinecarboxylic acid, 1008.
Naphthylidobutyric acid, α-, 1338.
Naphthylidobutyric acid, β-, 1338.
Naphthylidoisobutyric acids, derivatives of, 1342.
Naphthylidopropionic acid, α-, 1337.
Naphthylido-α-propionic acid, β-, 1337.
Naphthylimidazole, να-, 1331.

Naphthylimidazole-μ-mercaptan, να-, 1331.
Naphthylimidazolyl-μ-methyl sulphide, να-, 1331.
Naphthylmethyl chloride, α-, 494.
Naphthylmethylbiazolone, α-, 509.
Naphthylmethylbiazolone, β-, 508.
Naphthylmethylhydroxypyrimidine, 1009.
Naphthylmethylsulphone, β-, 623.
Naphthylmethyl-ψ-thiobiazolone, α-, 509.
Naphthylmethyl-ψ-thiobiazolone, β-, 508.
Naphthylmethylthiohydantoïn, α-, 150.
Naphthylphenylacetic acid, 1094.
Naphthylphenylacetonitrile, 1094.
Naphthylphenylbiazolone, α-, 509.
Naphthylphenylhydroxypyrimidine, 1009.
Naphthylphenylsemithiocarbazide, α-, 511; TRANS., 1019.
Naphthylphenylsemithiocarbazide, β-, TRANS., 1020.
Naphthylphenyl-ψ-thiobiazolone, α-, 510.
Naphthylquinoline, 1107.
Naphthylthiocarbamic acids, salts of, 56.
Naphthylthiocarbamide, α-, 1331.
Naphthylthiocarbizine, α-, 510.
Naphthylthiosemicarbazide, α-, 510.
Narcotine, reaction of, 756.
Nascent action, 257.
Natrolite from Magnet Cove, Arkansas, 793.
—— from Monte Baldo, 690.
Neodymium oxide, emission spectrum of, 2.
Nerves, heat production in, during excitation, 365.
Neurine, 219.
—— action of hydriodic and hydrobromic acids on, 808.
—— derivatives of, 806, 905.
Newtonite, 22.
Nickel, action of nitric acid on, 1278.
—— action of nitric oxide on, 1152.
—— ammonium sulphate, 1283.
—— atomic weight of, 1158.
—— carbonyl, oxidation of, 279.
—— —— physiological action of, 365.
—— detection of, 1525.
—— electrolytic separation of cadmium from, 920.
—— fluoride, 1159.
—— fluoroxyhypovanadate, 787.
—— nitrate, basic, 1157.
—— occlusion of hydrogen by, 567.
—— oxide, behaviour of, on strong heating, 1159.
Nickel potassium fluoride, 781.
—— reactions, 1132.
—— salts, action of alkaline polysulphides on, 537.
—— separation of iron from, 103.
—— separation of manganese from, 240.
—— sulphate, anhydrous, 1283.
—— —— —— crystallised, 941.
Nicotenylamidoxime, 206.
—— benzyl ether, 208.
Nicotenylazoximebenzenyl, 207.
Nicotenylazoximepropenyl-ω-carboxylic acid, 207.
Nicotenylazosulphimecarbanilide, 208.
Nicotenylphenyluramidoxime, 208.
Nicotiana tabacum, alkaloïds of, 232.
Nicotine, 1010, 1497.
—— action of bromine on, 1497.
—— action of silver acetate on, 1104.
Nicotinic acid, 3′-bromo-, 876.
Nipecotinic acid and its derivatives, 1485.
Nitramine of the quinoline group, attempted synthesis of, 725.
Nitrates, action of the copper-zinc couple on, in acid solution, 1518.
—— basic, 1157.
—— —— decomposition of, by water, 1272.
—— estimation of, in water, 243.
—— estimation of nitrogen in, 527, 528, 1517.
Nitrate-reducing ferment in straw, 1259.
Nitric acid, action of nascent hydrogen and nascent oxygen on, 680.
—— —— action of, on metals, 1278, 1402.
—— —— and lead, chemical changes between, 410.
—— —— colour of, 113.
—— —— gasometric estimation of, 1375.
—— —— manufacture of, 941.
—— —— reduction of, to ammonia by the galvanic current, 403.
—— —— separation of, from mercury and phosphoric and arsenic acids, 530.
—— —— tables revised, 13.
Nitric oxide, absorption coefficient of, in alcohol, 1044.
—— —— action of, on metallic oxides, 1151, 1271.
—— —— action of, on metals, 1151.
—— —— action of potash on, 940.
—— —— and oxygen, reaction between, 940.
—— —— behaviour of, at high temperatures, 940.
—— —— estimation of free oxygen by means of, 97.

Nitric oxide, preparation of, 939.
Nitric peroxide, action of, on metals and metallic oxides, 1390.
—— —— liquid, dissociation of, TRANS., 242.
Nitrification, comparative, of humus and undecomposed organic matter, 906.
—— in organic media of acid reaction, 906.
—— influence of clay and organic nitrogen on, in fallow soils, 656.
—— loss of nitrogen during, 374.
—— of organic nitrogen, 367.
Nitriles, action of sulphuric anhydride on, 713.
—— additive products of, with hydrogen iodide, 1448.
—— aromatic, 344.
—— —— formation of, 1094.
—— dimolecular, 450.
—— ketonic, action of hydroxylamine on, 79.
—— polymerisation of, 576.
—— refractive powers of, 757.
—— unsaturated, synthesis of, 1340.
Nitrites, action of the copper-iron couple on, in acid solution, 1518.
—— in water, influence of temperature on Griess' reaction for, 657.
Nitro-compounds, coloured, constitution of, PROC., **1892**, 101.
—— fatty, 575.
—— first product of the reduction of, 291, 594, 1067.
—— first product of the reduction of, with stannous chloride, 594, 1067.
Nitrogen, absorption coefficient of, in alcohol, 1043.
—— atmospheric, accumulation of, in cultivations of *Bacillus radicicola*, 1019.
—— —— assimilation of, 1507.
—— —— fixation of, by arable soils, 522.
—— Boyer's method of estimating, 1517.
—— compounds, stereochemical isomerism of, 338, 598.
—— —— stereoisomeric, dissociation constants of, 1268.
—— —— —— nomenclature of, 312, 875.
—— direct combination of, with the alkaline earth metals, 566.
—— dissolved in blood, 1257.
—— estimation of, 237, 751, 1125.
—— estimation of, in nitrates, 527, 528, 1517.
—— estimation of, in organic substances, 1516.
—— excretion of, in kidney diseases, 743.
Nitrogen, excretion of, in urine, 1503.
—— for plants, rain as a source of, 233.
—— free, assimilation of, by plants, 367, 370, 378, 523.
—— —— fixation of, by leguminous plants, 369.
—— —— —— fixation of, by plants, 1021.
—— —— fixation of, during vegetation, 1508.
—— influence of hot baths on the excretion of, from the human system, 1503.
—— influence of water and sodium chloride on the excretion of, 904.
—— loss of, in the decomposition of nitrogenous matters in the soil, 374.
—— of leguminous crops, sources of the, 367.
—— organic, estimation of, 527.
—— —— nitrification of, 367.
—— question, 374.
—— rings containing, nomenclature of, 312, 875.
—— solubility of, in water, 108, 271.
Nitrogen-free extract, constituents of, 653.
Nitro-group, displacement of the, by chlorine or bromine, 305.
—— first reduction products of, 291, 594, 1067.
Nitro-metals, 1390.
Nitrosilicic acid, existence of, 684.
Nitrosoazo-compounds, constitution of, 1321, 1453.
Nitrosulphonic acids, preparation of, 475.
Nitrous acid, detection of, 1124.
—— —— estimation of, 751, 1029.
Nitrous oxide, absorption coefficient of, in water and in alcohol, 1044.
Nomenclature, international system of, PROC., **1892**, 127.
—— of cycloïds, PROC., **1892**, 127.
—— of rings containing two carbon and three nitrogen atoms, 889.
—— of stereoisomeric nitrogen compounds and of rings containing nitrogen, 312, 875.
Nonenylamidoxime, 132.
Nononaphthene, action of nitric acid on, 443.
—— amido-, 443.
—— ketonic compound from, 443.
—— nitro-, 443.
Nonylamine, 132.
—— action of nitrous acid on, 132.
Nonylcarbamide, 132.
Nonyldithiocarbamic acid, 132.
Norhemipinic acid, meta-, 180.
Nucleïc acid and guanine, supposed compound of, 1501.

Nucleïn, 224, 1501.
—— formation of uric acid from, 646.
Nutrition, influence of, on the assimilation of free nitrogen by plants, 371.
—— influence of, on the composition of the blood ash, 225.
—— of green plant cells with formaldehyde, 1259.

O.

Oat, proteïds of the, 1120.
Occlusion of hydrogen by palladium: lecture experiment, 563.
Octahedrite, 1055.
Octopus vulgaris, blood of, 648.
Octyl acetate, secondary, 1162.
—— iodide, refractive power of, at different temperatures, Trans., 295.
Œnanthaldehyde, action of zinc and ethyl chloracetate on, 1300.
—— condensation of, with aniline, 1194.
Œnanthaldoximes, 1436.
Œnanthantialdoxime, 1436.
Œnocarpol, 874.
Oil, essential, of Angostura bark, 644.
—— —— of *Licari kanali*, 1236.
—— kuromoji, 1480.
—— lard, iodine number of, by Hübl's method, 664.
—— of ants, composition of, 948.
—— of bergamot, 349, 868, 1235.
—— —— stearoptene of, 71.
—— of cassia, estimation of cinnamaldehyde in, 924.
—— of cinnamon, 1509.
—— of cloves, valuation of, 250.
—— of laurel, 722.
—— of lavender, 868, 1235, 1347.
—— of lime seed, 92.
—— of mustard, estimation of, 1035.
—— of peppermint, Russian, 723.
—— of petitgrain, 868.
—— of roses, German and Turkish, 203, 625.
—— sesame, detection of, in olive oil, 1133.
—— volatile, from *Aristolochia reticulata*, 70.
Oils and fats, revision of constants employed in the analysis of, 547.
—— essential, 1347.
—— ethereal, oxygen compounds of, 868.
—— fat, absorption and digestion of, by plants, 1118.
—— fatty and mineral, detection of rosin oil in, 548.
—— lubricating, rapid determination of the composition of, 665.
Oils, mineral, heavy, determination of the flashing point of, 542.
—— of lemon and bergamot, crystalline products from, 349.
—— vegetable, detection of, in lard, 1133.
Olefines, action of fatty acids on, 1162.
Oleïc and elaïdic acids, stereoisomerism of, 812.
Olive oil, detection of sesame oil in, 1133.
Onions, Spanish, cooked, composition of, Trans., 227.
Ononis arvensis, composition of, 522.
Oölitic iron ore of Lorrain, microscopic structure of, 791.
Opianic acid, 179.
—— —— action of acetone on, 179.
—— —— action of acetophenone on, 179.
—— —— bromo-, 1209.
—— —— oxime of, 180.
—— anhydride, oxime of, heat developed in the isomeric change of the, 459.
—— hydrazobenzene, brom-. 1210.
—— methylphenylhydrazone, brom-, 1210.
—— phenylhydrazide, brom-, 1210.
Opianoximic anhydride, brom-, 1210.
Opium, assay of, 926.
Optical chemistry, application of Ketteler's formulæ to, 253.
Optically active substances, behaviour of, in mixtures of two solvents, 1137.
Oranges, Californian, analyses of, 1511.
Orcinol, compound of, with phenylhydrazine, 49.
Organic compounds, magnetism of, 672.
—— matters in the atmosphere, estimation of, 542.
—— substances, estimation of nitrogen in, 1515, 1516.
Organism, fœtal, iron in the, 1502.
—— formation of glucose and lactic acid in, 517, 1113.
—— formation of sugar in the, when oxygen is deficient, 362.
—— living, action of azoimide on, 90.
Organosols, 775.
Orobus niger, composition of, 522.
Orpiment, analysis of, 657.
—— from the Yellowstone National Park, 283.
Oscine, 1498.
Osmium, electrolytic separation of gold, of cadmium, of silver, and of mercury from, 920.
Osmosis, absorption without, 646.
Osmotic pressure and electrolytic dissociation, theories of, 1143.
—— —— measurement of, 556.
—— —— theory of, 676, 765.

Ox gall, presence of myristic acid in, 1114, 1503.
Oxalates, absence of, in young leaves, 651.
Oxalic acid, formation and physiological significance of, in fungi, 230.
—— chloride, 588.
—— diphenylhydrazide, 981.
Oxal-β-naphthalide, dinitro-, Trans., 466.
Oxalorthotoluidide, dinitro-, Trans., 463.
—— tetranitro-, Trans., 464.
Oxalparatoluidide, tetranitro-, Trans., 465.
Oxalyl-β-naphthylhydrazine, 509.
Oxalylorthamido-α-naphthyl mercaptan, 1079.
Oxalylorthamidophenyl mercaptan, 1079.
Oxamethanetolyloxamide, 603.
Oxamethanetolylurethane, 601.
Oxamidotolylurethane, 601.
Oxanilic acid, dinitro-, Trans., 468.
—— —— nitro-, Trans., 468.
—— —— trinitro-, Trans., 469.
Oxanilide, action of nitric acid on, Trans., 458.
—— and its homologues, preparation of, Trans., 459.
—— hexanitro-, Trans., 462.
—— —— hydrolysis of, Trans., 462.
—— tetranitro-, Trans., 460.
—— —— hydrolysis of, Trans., 461.
Oxazine-dyes, 887.
Oxazole, 313.
Oxazolines, 213.
—— formation of, 1331.
Oxetone, 813.
Oxetonedicarboxylic acid, 813.
Oxidation, physiological, 1018.
—— spontaneous, of humic acid and vegetable soil, 655.
Oxides, metallic, action of boron on, 1154.
—— —— action of nitric oxide on, 1151, 1271.
—— —— —— action of nitric peroxide on, 1390.
Oximes, 1080.
—— action of, on diazo-compounds, 163, 1079.
—— and the so-called stereochemistry, 50.
—— isomeric, 1083.
—— isomerism of, 291.
—— relations between the constitution, configuration, and chemical behaviour of, 1175.
Oximidoacetic acid, 699.
Oximido-acids, dissociation constants of, 1268.
Oxole, 313.
Oxyacanthine, 641.
Oxyacetoindigotin, 991.
Oxyamidosulphonates, action of alkali on, Trans., 988.
Oxy-α-amyrin, 290.
—— acetate, 290.
Oxyazo-compounds, 974.
Oxycellulose, 827.
Oxychrysanthemine, 85.
Oxydehydracetic acid, 585.
Oxygen, aldehydic and ketonic, estimation of, 546, 1530.
—— and carbonic oxide, influence of steam and other gases on the combustion of, 274.
—— and chlorine, reaction of, with hydrogen, 1147.
—— and hydrogen, admixed, slow combustion of, 938.
—— —— compounds of the elements, correlation of, 1270.
—— and nitric oxide, reaction between, 940.
—— atomic weight of, 1388.
—— combination of hæmoglobin with, 1369.
—— dissolved in water, estimation of, 98; Trans., 310.
—— free, estimation of, by means of nitric oxide, 97.
—— —— Schützenberger's process for the estimation of, 98.
—— influence of, on alcoholic fermentation, Trans., 339.
—— influence of, on the separation of carbonic anhydride in the lungs, 1369.
—— solubility of, in water, 108, 271.
Oxyhæmoglobin crystals, oxygen in, 1017.
—— formation of, from hæmatin and a proteïd, 1017.
—— solutions of, Trans., 158.
Oxy-hydrogen gas, absorption of, by soil, 377.
—— —— action of light on, 939.
—— —— ignition temperature of, 680.
—— —— lecture experiments on the combination of, 562.
Oxymercuric hydrogen imidosulphonate, Trans., 977.
—— sodium imidosulphonate, Trans., 983.
Oxymethylenemethoxybutenylbenzene, 311.
Oxymethylquinolines, nitroso-, 727, 728, 729.

P.

Pæonol, 58.
—— phenylhydrazone, 59.
Pæonoloxime, 59.
Pa'inurus vulgaris, blood of, 648.
Palladious oxide, 572.
Palladium, absorption of oxygen by, 943.
—— action of nitric acid on, 1152.
—— atomic weight of, TRANS., 745.
—— direct oxidation of, 572.
—— lowering of the freezing point of bismuth by, TRANS., 894.
—— lowering of the freezing point of cadmium by, TRANS., 900.
—— lowering of the freezing point of lead by, TRANS., 906.
—— occlusion of hydrogen by, 567.
—— occlusion of hydrogen by: lecture experiment, 563.
—— nitrogen compounds, 1284.
Pallasites, the prehistoric and Kiowa Co., 1059.
Palmitic acid, action of bromine on, 696.
Pancreas extract, presence of pentamethylenediamine in, 1368.
Paper, drawing, the acid action of, PROC., **1892**, 19, 34.
—— wall-, estimation of arsenic in, 382.
Paracoto bark, constituents of, 62, 873.
Paraffin-derivatives, boiling points of, 797.
Paraffins, normal, boiling point curves for, 947.
Paraldehyde, condensation of, with chloral, 694.
Paramelaconite, 415.
Paranthracene, 347.
Parapectic acid, 291.
Parapropaldehyde, 1300.
Parsnips, cooked, composition of, TRANS., 227.
Pea-nut, 1122.
Peas, assimilation of free nitrogen by, 371, 372, 374, 378.
—— cooked, composition of, TRANS., 227.
Pectic acid, so-called artificial, from fir-wood, 827.
Pectin-substances, 291.
Pedetic motion in relation to colloïdal solutions, PROC., **1892**, 17.
Penicillium glaucum, action of, on fumarates and maleates, 820.
—— —— resolution of inactive lactic acid by, 297.
Pentabenzoylglucosamine, 134.
Pentacetylxylitol, 29.
Pentadecylacridine, 343.
Pentahydroxyaurindicarboxylic acid, 1469.
Pentahydroxypimelic acid, 1169.
Pentamethylbenzene, chloro-, 968.
Pentamethyldihydroquinoline, 615.
Pentamethylene glycol and its oxides, 1292.
Pentamethylenediamine, 1368.
—— hydrogen diaminechromium thiocyanate, 1001.
—— platinothiocyanate, 287.
Pentamethylenedicarboxylic acid, β-, dissociation constant of, TRANS., 706.
Pentamethylenedicarboxylic acid [1 : 2], melting point of, 1040.
—— —— thermochemistry of, 1041.
Pentamethylethyltrimethylenetrisulphone, 593.
Pentamethyltetrahydroquinoline, 615.
Pentane flame, experiments on, TRANS., 210.
Penterythritol, 127.
—— thermochemistry of, 764.
Pentethylphloroglucinol, bisecondary, oxidation of, 1188.
Pentonic acid, new, 437.
Pentosans of woody vegetable fibre, 1420.
Pentose carbohydrates, digestibility of, 645.
Pentoses, detection of, in vegetable products, 250.
—— estimation of 247, 388.
—— physiological action of, 1506.
Pentoxazolines, 213.
Peppermint oil, Russian, 723.
Peptone, decomposition of, in the human body, 904.
—— salts from glutin, 895, 1016.
Peptones, analysis of, 1535.
—— constitution of, 1499.
—— estimation of, in stomach contents, 1136.
—— formation of sugar from, in blood, 1502.
—— in the blood and organs of leucæmic patients, 519.
—— molecular weights of, 1501.
—— salicylsulphonic acid as a test for, 552.
—— volumetric estimation of, in urine, 1264.
Peridotite in Central New York, 1057.
Periodic relations of the elements, 562.
Permanganate solutions, stability o 1524.
Permanganates and hydrogen peroxide, reaction between, 277.

Permeability of precipitated membranes, 1383.
Permolybdates, 1160.
Permolybdic acid, 1283.
—— —— heat of formation of, 1383.
Perruthenates, action of heat on, 282.
Perseïtol, compounds of, with molybdic acid, 422.
—— hydrocarbon derived from, 1065.
—— rotatory power of compounds of, with sodium hydrogen and ammonium hydrogen molybdate, 800.
—— thermochemistry of, 764.
Persulphates, 12.
Persulphuric acid and its salts, 931.
Petalite from Maine, 1411.
Petitgrain, oil of, 868.
Petroleum, pyridine-like bases in, 1357.
Phanerogams, assimilation of free nitrogen by, 370.
Phenacetin, detection of, in urine, 665.
—— orthonitro-, 160.
Phenacetyl-αβ-diphenylacrylamide, β-, 483.
Phenacetyl-αβ-diphenylacrylethylamide, β-, 484.
Phenanthrene and picric acid, solubility relations of the compound of, 1384.
Phenanthridine, 196.
—— methohydroxide, 197.
Phenetoïl, dibromonitro-, 1182.
—— paramido-, oxidation products of, 158.
—— sulphonic acids derived from, Proc., **1892**, 90.
Phenetidine, para-, oxidation products of, 158.
—— —— orthonitro-, 160.
Phenol, action of phospham on, 1311.
—— alkalimetric estimation of, 543.
—— depression of the melting point by, 556.
—— dinitrosonitro-, 594.
—— diorthochloroparabromo-, Trans., 560.
—— metabromonitro-, reduction of, 704.
—— metachlorothio-, 306.
—— orthochlorothio- 308.
—— parachlorothio-, 308.
—— thermal function of, 1042.
—— thermochemistry of, 764, 1042.
Phenoldisazobenzene, constitution of, 976.
Phenoldisazo-orthobenzeneparatoluene, 976.
Phenoldisazoparabenzeneorthotoluene, 976.
Phenoldisazotoluene, 976.
Phenolic acids, instability of carboxyl in, 1332.
Phenolphthaleïn ethyl ether, 1096.
Phenolphthalin ethyl ether, 1319.
Phenols, action of chlorine on, 1186.
—— action of methylchloroform and ethylchloroform on alkaline solutions of, 308.
—— action of phenylhydrazine on, 49.
—— amido-, condensation products of, 1451.
—— and unsaturated hydrocarbons, condensation of, 446, 1443.
—— condensation of, with isoamylene and cinnamene, 447.
—— estimation of, in human urine, 544.
—— isomeric change in the synthesis of, 44.
—— polyhydric, action of dinitrochlorobenzene on, 210.
—— thermochemistry of, 763.
Phenonaphthacridone, 1477.
Phenonaphtho-xanthone, 1099.
Phenoparatolyldihydrotriazine, β-, 734.
Phenophenyldihydrotriazine, γ-, 734.
Phenoquinolino-xanthone, 1099.
Phenoquinoxazine, 887.
Phenoquinoxazone, 887.
Phenotriazines, synthesis of, 734.
Phenoxyamylamine, ε-, 717.
Phenoxybutylamine, γ-, 131.
Phenoxybutyronitrile, γ-, 131.
Phenoxypropylmalonic acid, 717.
Phenoxyvaleric acid, γ-, 717.
Phenoxyvaleronitrile, γ-, 717.
Phenyl bromide, refractive power of, at different temperatures, Trans., 299.
—— chloride, refractive power of, at different temperatures, Trans., 298.
—— dithiocarbonate, chloro-, 306, 307.
—— —— parachloro-, 307.
—— dithiocarbonates, 306.
—— iodide, refractive power of, at different temperatures, Trans., 300.
—— isocyanide, preparation and properties of, 1438.
—— α-naphthyl ketone, sodium derivative of, 170.
—— orthacetate, 308.
—— orthomethoxytolyl ketone, 446.
—— phenyl-β-naphthylcarbamate, 166.
—— sodium sulphite, 970, 1076.
—— —— —— action of iodoform on, 1076.
—— thiodi-β-naphthylcarbamate, 166.
—— thiodiphenylcarbamate, 164.
—— xanthate, chloro-, 308.
Phenylacetaldoxime, 1174.
Phenylacetic acid, preparation of, 344.
—— diphenylhydrazide, 981.
Phenylacetometachloranilide, 1465.
Phenylacetoparatoluidide, 1465.
Phenylacetorthotoluidide, 1465.
Phenyl-α-acetoxycrotonic acid, γ-, 472.

Phenylacetylene, silver derivative of, 831.
Phenylacridine, ammonium bases of, 1095.
—— diamido-, preparation of, 1095.
Phenylacridinemethylium ethoxide, 881.
—— hydroxide, 881.
Phenyl-β-alanine, 1342.
Phenylamidoacetic acid, derivatives of, 467.
—— anhydride, 468.
Phenylamidomesoxalic chloride, 1439.
Phenylamidophenylinduline, 342.
—— amido-, 342.
Phenylamines, substituted, action of silicon tetrachloride on, Trans., 453.
Phenylamphiglyoxime, anti-, 321.
Phenylamphiglyoximecarboxylic acid, 1177.
Phenylangelicalactone, 987.
Phenyl-α-anilidocrotononitrile, 1194.
Phenylanthracene, preparation of, 722.
Phenylanthranilic acid, 1086.
Phenylantiglyoxime, 321.
Phenylazimidobenzene, 889.
—— amido-, 1322.
—— tetranitro-, 1454.
Phenylazorthohydroxymethylquinoline, meta-, 506.
Phenylazoxazole, 322.
Phenylazoxazolecarboxylic acid, 1178.
Phenylazoximidobenzene, tetranitro-, 1454.
Phenylbenzenylamidine, 51.
Phenylbenzenylnaphthylenediamine, 1472.
Phenylbenzimidoethyl ether, 52.
Phenylbenzophenone, para-, derivatives of, 186.
Phenylbenzophenoneoxime, para-, 186.
Phenylbenzophenonephenylhydrazone, para-, 186.
Phenylbenzoylbromomethylpyrazolone [1 : 2 : 4 : 3-], 146.
Phenylbenzoyldimethylpyrazolone, 146.
Phenylbenzoylmethylpyrazolone, [1 : 2 : 3-], 146.
Phenylbenzylformamidine, 708.
Phenyl-4-benzylidene-3 : 5-pyrazolidone, 1-, 1005.
Phenylbenzylparatolylcarbamide, 1083.
Phenylbenzylthiourea, unsymmetrical, Proc., **1892**, 97.
Phenylbromobutyrolactone, 987.
Phenylbromodihydroxybutyrolactone, 1447.
Phenyl-γ-bromo-α-hydroxybutyric acid, γ-, 471.
Phenylbromohydroxycrotonic acid, 1447.
Phenylbromotrimethylene-ψ-thiourea, *n*-, Trans., 550.
Phenyl-γ-bromovaleric acid, 988.
Phenylbromovalerolactone, 987.
Phenylcarbamide and its derivatives, 480.
—— bromo-derivatives of, 467.
Phenylchloracetonitrile, 1088.
Phenylcinnamonitrile, 344.
Phenylcroton-α-lactone, γ-, 472.
Phenyldibenzoylmethylpyrazolone [1 : 2 : 4 : 3-], 146.
Phenyl-2 : 4-dibenzoyl-3 : 5-pyrazolidone, 1-, 1005.
Phenyldibenzylcarbamide, 1083.
Phenyldibromobutyric acid, decomposition of, 987.
Phenyldibromohydroxybutyronitrile, 1447.
Phenyldibromovaleric acid, decomposition of, 987.
Phenyldifurylnaphthodihydroquinoxaline, 1475.
Phenyldihydroxybutyric acid, 986.
Phenyl-αγ-dihydroxybutyrolactone, γ-, 472.
Phenyldihydroxyvaleric acid, 986.
Phenyldimethylisopyrazolone, 635.
Phenyldimethylpyrazolidone, 731.
Phenyldimethylthiohydantoïn, 150.
Phenyl-β-dimethyl-μ-thiomethylimidazole, ν-, 153.
Phenyldimethylthiourea, Trans., 539.
Phenyldiorthocresolmethane, meta-nitro-, 621.
Phenyldithiobiuret, α-, 704, 844.
Phenyldithiocarbamic thioanhydride, 55.
Phenyldithiodimethylketuret, α-, 844.
Phenylene hydrogen antimonite, ortho-, 1078.
—— orthotolylcarbamate, meta-, 832.
—— oxide, 1187.
Phenylenediamine, meta-, preservation of solutions of, and its use as a reagent, 1124.
Phenylenediamine, ortho-, action of formaldehyde on, 1496.
Phenylenediphenylpropionic acid, 1228.
Phenylenehydroxylamine, dinitro-, 594.
Phenylethenylamidoximebenzenesulphone, 461.
Phenylethenyldiamidoacetone, 952.
Phenylethyltriazolecarboxylic acid, 637.
Phenylfurazan, 322.
Phenylfurfurylcarbamide, 43.
Phenylfurfurylthiocarbamide, 43.
Phenylglyceric acid, 986.
Phenylglycocine, derivatives of, 1333.
Phenylglycollic acid, action of nitric acid on, 607.
—— —— orthoparadinitro-, 1333.

Phenylglyoximes, 321.
Phenylguanazole, 356.
Phenylguanidine picrate, 950.
Phenylgulosazone, 1-, 823.
—— parabromo-, 823.
Phenylhexyltriazolecarboxylic acid, 597.
Phenylhippuric acid, 468.
Phenylhydantoïn, γ-, 828.
Phenylhydrazidobutyramide, α-, 1192.
Phenylhydrazidopropionic acid, α-, 1196, 1456.
—— nitrile, 1195.
Phenylhydrazimethylenecarboxylic acid, ammonium salt of, 453.
Phenylhydrazine acetate, 981.
—— action of arsenic chloride on, 1326.
—— action of boron chloride on, 1326.
—— action of copper sulphate on hot acid solutions of, 842.
—— action of cyanogen chloride on, 1323.
—— action of, on carbamide, 1323.
—— action of orthonitrobenzyl chloride on, 1455.
—— action of phosphorus trichloride on, 1324.
—— action of silicon chloride on, 1326.
—— carbonyl chloroplatinite, 353.
—— derivatives of, 453.
—— hydrogen diaminechromium thiocyanate, 1001.
—— inorganic derivatives of, 1324.
—— metachloro-, and its derivatives, 454.
—— metallic derivatives of, 1454.
—— oxidation of, with Fehling's solution, 1322.
—— parahydroxyalkyl derivatives of, 1198.
—— paralkyloxy-derivatives of, 1080.
—— parathio-, 1326.
—— paratolylphosphenite, 1325.
—— phosphenite, 1325.
—— phosphite, 1325.
—— thionylthio-, 1326.
Phenylhydrazinebutyric acid, asymmetrical, 635.
Phenylhydrazolepidine, 2-, 1488.
Phenylhydrindone, 1220, 1228.
Phenylhydrocinnamic acid, α-, 1211.
Phenylhydroxyacetonitrile, acetyl derivative of, 1088.
Phenylhydroxybenzenylnaphthylenediamine, 1472.
Phenylhydroxybutyrolactone, 986.
Phenyl-α-hydroxybutyro-γ-lactone, γ-, 472.
Phenyl-α-hydroxycrotonic acid, 471.
Phenylhydroxyformamidine, 708.
Phenylhydroxyphenylethane, 446.
Phenyl-γ-hydroxyvaleric acid, 988.
Phenylhydroxyvalerolactone, 986.
Phenylimidocarbonyl chloride, 1430.
Phenylimidodiacetic anhydride, 1334.
Phenylimidoformic chloride hydrochloride, 1440.
Phenylimidopyruvic chloride, 1440.
Phenylindole, 2′-, 1465.
—— chloro-2′-, 1466.
Phenylinduline, action of acetic acid on, 341.
—— amido-, action of sulphuric acid on, 341.
Phenylisobromobutyrolactone, 987.
Phenylisocrotonic acid, 850.
—— —— oxidation of, 986.
Phenylisodihydroxybutyric acid, 1448.
—— —— salts of, 987.
Phenylisohydroxybutyrolactone, 987.
Phenyl-4-isonitroso-3 : 5-pyrazolidone, 1-, 1005.
Phenylisopropylbenzenylnaphthylenediamine, 1473.
Phenyl-4-isopropylene-3 : 5-pyrazolidone, 1-, 1005.
Phenylisopropyltriazolecarboxylic acid, 638.
Phenylisoxazolone, 1177.
Phenylketodihydroquinazoline, 81.
Phenylketodihydroquinazolinecarboxylic acid, 81.
Phenylketohydroxybutyric acid, 1448.
Phenyllevulinic acid, 988.
Phenyllupetidinedicarboxylic acid, 1487.
Phenyllutidinedicarboxylic acid, 1486.
Phenylmetachlorazobenzene, nitro- and nitronitroso-derivatives of, 454.
Phenylmetachlorazoxybenzene, nitronitroso-, 455.
Phenylmetachlorophenylhydrazine, orthoparadinitro-, 454.
Phenylmetahydroxytolylethane, 446.
Phenylmetamethoxytolylethane, 446.
Phenylmetanitrobenzenylamidine, 52.
Phenylmetanitrobenzenylnaphthalenediamine, 1473.
Phenylmetanitrobenzimido ether, 52.
Phenylmethaneazobenzene, orthonitro-, 1456.
Phenyl-α-methoxy-β-methyl-μ-thiomethylimidazole, ν-, 152.
Phenylmethylbenzoylpyrazolone [1 : 3 : 4-], 146
Phenylmethylenehydrazine, 456.
Phenylmethylethylpyrazole platinochloride [1 : 4 : 5-], 885.
Phenylmethylhydroisopyrazolone, 635.
Phenylmethylisopyrazolone, 635.
Phenylmethylmethylenehydrazine, 457.
Phenylmethylphenylazimethylene, 457.

Phenylmethylpyrazolidone, 731.
Phenylmethylpyrazolone, constitution of, 634.
—— mono-, di-, and tri-bromo-, 731.
—— nitro-, 731.
Phenylmethylthiohydantoïn, 150.
Phenylnaphthostilborosindone, 1247.
Phenylnaphthylenediamine, ortho-, action of benzaldehyde on, 1472.
—— —— action of salicylaldehyde on, 1472.
Phenyl-α-naphthylformamidine, 706.
Phenyl-α-naphthylglycollic acid, 170.
Phenyl-β-naphthylsemithiocarbazide, Trans., 1020.
Phenyl-β-naphthylthiocarbamide, 984.
Phenyl-β-naphthylthiosemicarbazide, 508.
Phenylnonylcarbamide, 132.
Phenylnonylthiocarbamide, 133.
Phenylorthohydroxytolylethane, 446.
Phenylorthomethoxytolylethane, 446.
Phenylorthonitrobenzenylnaphthylenediamine, 1473.
Phenyl-3 : 6-orthopiperazone, 1-, 1494.
Phenyloxazoline, μ-metanitro-, 213.
—— preparation of, 1832.
Phenyloximidoacetonitrile, 322.
Phenylparaditolylcarbamide, 1083.
Phenylparanitrobenzenylnaphthalenediamine, 1473.
Phenylparaphenylglycoluric acid, 828.
Phenylparatolylthiosemicarbazide, Trans., 1014.
Phenylpentoxazoline, μ-, 212.
—— μ-metanitro-, 214.
Phenylpentriazole, meso-, 889.
Phenylphthalimide, preparation of, 1204.
Phenylpiperazine, paranitro-, 210.
Phenylpropiolic acid dichloride, 1464.
—— —— formation of allocinnamic acid from, 848.
Phenylpropionic acid, formation of a hydrocarbon, $C_{18}H_{12}$, from, Proc., 1892, 107.
Phenylpropylamine, 845.
Phenylpropyltriazolecarboxylic acid, 638.
Phenylpyrazolidine, 355.
Phenyl-3 : 5-pyrazolidone, 1-, 1004.
Phenyl-3 : 5-pyrazolidone-4 azobenzene, 1-, 1005.
Phenylpyrazolone, 799.
Phenylpyrazolonecarboxylic acid [1 : 5 : 4], Trans., 797, 799.
Phenylpyridone, αββ-trichloro-γ-, 448.
Phenyl-γ-pyridonecarboxylic acid, αββ-trichloro-, 448.
Phenylpyrrodiazolecarboxylic acid, 1 : 3-, synthesis of, 636.
Phenylquinoline, α-, derivatives of, 1003.
Phenylsantoninmethane, metanitro-, 622.
Phenylsemicarbazide, 1323.
Phenylsuccinamidine, 702.
Phenylsuccinimide, preparation of, 1204.
Phenylsulphone-δ-amidovaleric acid, 354.
Phenylsulphonehydroxypropionic acid, parachloro-, 1091.
Phenylsulphonepropionic acid, α-amido-, 1091.
Phenylsulphonetetrahydroquinoline, 355.
Phenylsynglyoxime, 322.
Phenylsynglyoximecarboxylic acid, 1177.
Phenyltetrahydroketoquinazoline, 1495.
Phenyltetrahydroketoquinoxaline, 886.
Phenyltetrahydroketotoluquinoxaline, 886.
Phenyl-Δ²-tetrahydro-2-methylpyridine, 1-, 1244.
Phenyl-Δ²-tetrahydropicoline, 1-, 1244.
Phenyltetrahydrothioquinazoline, 1495.
Phenyltetrazolecarboxylic acid, amido-, 1009.
—— —— nitro-, 1009.
Phenyltetrazolecarboxylthiamide, 638.
Phenyltetrose, 1447.
Phenylthiocarbamide, 465.
Phenylthiocarbamides, thio-, melting points of, 324.
Phenylthiocarbamineisobutylcyamide, 703.
Phenylthiocarbimide, action of dimethylaniline on, Trans., 538.
—— and chloral-ammonia, Trans., 529.
—— compound of, with aldehyde-ammonia, action of silver nitrate on the, Trans., 518.
Phenylthiocarbimide-aldehyde-ammonia, Trans., 521.
Phenylthiourethane, 600.
Phenyltoluene, meta-, 851.
Phenyltriazolecarboxylic acid, amido-, 735.
—— —— nitro-, 735.
Phenyltrihydroxybutyric acid, 1447.
Phenyltrihydroxybutyrolactone, 1447.
Phenyltrimethylenecarboxylic acids, 849.
Phenyltrimethylene-2 : 3-dicarboxylic acid, Γal-, 849.
Phenyltrimethylene-2 : 2 : 3-tricarboxylic acid, Γal-, 849.
Phenyltrimethylmethane, paramido-, 44.
Phenyltrimethylphenylacetonitrile, 1094.

Phenyltri-β-naphthylcarbamide, 167.
Phenylumbelliferone, reduction of, 1228.
Phenyluranilidacetic acid, 468.
Phenylurazole, preparation of, 966.
Phenylvalerolactone, 988.
Phloroglucinol, presence and function of, in plants, 1120.
Phœnicrocoïte, synthesis of, 792.
Pholidolite, 1408.
Phosphamide, 1152.
Phosphates, analysis of, 99, 912.
—— estimation of, 1125.
—— estimation of calcium in, 534.
—— estimation of iron and aluminium in, 536.
—— natural, fluorine in, 1055.
Phosphenylbenzylphenylhydrazone, 1325.
Phosphenylparatolylhydrazone, 1325.
Phosphenylphenylhydrazine, 1325.
Phosphines, tertiary, action of benzal chloride on, 984.
Phosphinobenzene, 1084.
Phosphino-compounds, 1084.
Phosphino-ψ-cumene, 1085.
Phosphinoparatoluene, 1085.
Phosphonium bromide, dissociation of, 401.
Phosphopalladious compounds, 1285.
Phosphoric acid, assimilation of, by crops from the soil, 233.
—— —— basicity of, 394.
—— —— estimation of, by the molybdate process, 1519.
—— —— estimation of, in fertilisers containing cotton seed meal, 1029.
—— —— estimation of, in manures, 1125.
—— —— estimation of, in slags, 382.
—— —— estimation of, in soil, 750.
—— —— estimation of iron and aluminium in the presence of, 755.
—— —— in soil, 750.
—— —— in urine, 1115.
—— —— reverted, estimation of, 1126.
—— —— separation of, from mercury, sodium, chlorine, and from nitric acid, 530.
—— —— volumetric estimation of, 912.
Phosphorous acid, dihydrazide of, 1325.
Phosphorus, allotropic states of, 405.
—— analysis of a slag from the manufacture of, in electrical furnaces, 1401.
—— and sulphur, compounds of, 14.
—— bromonitride, 1272.
—— chloronitride, 1152, 1172.
—— compounds, organic, 875.
—— dilatation of, and its change of volume at the melting point, 7.
Phosphorus, estimation of, in iron, steel, and iron ores, 528, 529.
—— estimation of, in pig iron, 912.
—— poisoning, the urine in a case of, 650.
—— precipitation of, from solutions of iron and steel, 911.
—— trifluoride, action of fluorine on, 12.
Phosphorylphenylhydrazide, 1325.
—— thio-, 1326.
Phosphoryltolylhydrazide, 1325.
Phosphotungstic acids, 1160.
Photometry, colour-, Proc., **1891**, 150.
Phthalamidones, 1248.
Phthalic acid, reduction products of, 1211.
Physical phenomena at very low temperatures, 1138.
Physiological action and chemical constitution of aromatic compounds, relation between, 366.
—— —— of calcium β-naphthol-α-sulphonate, 1116.
—— —— of camphors and of their compounds with chloral, 227.
—— —— of choline, neurine, and allied compounds, 905.
—— —— of dinitrobenzene, 366.
—— —— of gallic and tannic acids, 904.
—— —— of impure chloroform, 745.
—— —— of ketones and acetoximes, 1506.
—— —— of nickel carbon oxide, 365.
—— —— of pentoses, 1506.
—— —— of quinone and quinone derivatives, 1115.
—— —— of sulphonal, 1507.
—— —— of sulphones, 153.
—— —— of strontium salts, 227.
—— —— of triazobenzene, benzamide, α-acetonaphthalide, and ethyl α-naphthylazoacetoacetate, 366.
—— —— of trimethylamine, 366.
Physiological oxidation, 1018.
Phytosterin, 1294.
Picea vulgaris, resin from, 205.
Picene, 623.
Picoline, α-, preparation of α- and β-pyridyllactic acids from, 75.
—— dichloro-, Trans., 725.
—— hydrogen diaminechromium thiocyanate, 1001.
Picric acid, bromination of, 156.
Picroaconitine, 1254.
Picrotin, action of hydriodic acid and phosphorus on, 349.
Picrotoxic acid, 349.
Picrylmetachlorazobenzene, 454.
Picrylmetachlorophenylhydrazine, 454.
Pigs fed on corn cockle, metabolism in, 1018.

Pillijanine, 894.
Pilocarpine, action of, on the excretion of milk, 365.
—— hydrogen diaminechromium thiocyanate, 1901.
Pimelic acid, derivatives of, 428.
—— —— dissociation constant of, Trans., 700.
—— —— thermochemistry of, 1041.
—— anhydride, dihydrazido-, 435.
Pinacone, thio-, 1317.
Pineapple juice, ferments in, 650.
Pinene, constitution of, 865, 997.
Pinenenitrolallylamine, 998.
Pinenenitrolamylamine, 998.
Pinenenitrolbenzylamine, 998.
Pinenenitrolpropylamine, 998.
Pinna squamosa, ash of the blood of, 1016.
—— —— blood of, 649.
Pinnaglobin, a new globulin, 1016.
Pinone glycol and its derivatives, 998.
Pinus abies, terpenes from the resin of, 625.
—— *laricio*, resin from, 204.
—— *sylvestris*, pollen of, 232.
Pinylamine, 996.
Pinylcarbamide, 997.
Piperazine, 210.
—— dichloro-, 211.
Piperidine and furfuraldehyde, condensation of, 1452.
—— argento-salts, 1483.
—— chloriodide, 1357.
—— derivatives of, oxidation of, 354.
—— oxidation of, 1104.
—— oxidation of, by hydrogen peroxide, 1484.
—— synthesis of, 717.
—— thiocyanate, 1110.
Piperidine-bases of the β-series, 628.
Piperidinecarboxylic acids, 1486.
Piperonalamidoxime, 318.
Piperonaldoxime, 318.
Piperonalonitrile, 318.
Piperylacetoguanamine, 736.
Piperylbiguanide, 735
Piperylformoguanamine, 735.
Pipette for weighing fuming liquids, 13.
—— gas-, improved, 1374.
—— improved for gas absorptions, 1124.
Pisum arvense, composition of, 522.
Plant food, sodium as a, 1508.
Plant-cells, green, nutrition of, with formaldehyde, 1259.
Plants, absorption and digestion of fat oils by, 1118.
—— assimilation of free nitrogen by, 367, 370, 378, 523.
—— direct absorption of ammoniacal salts by, 229.
Plants, fat-decomposing ferments in, 1261.
—— fixation of free nitrogen by, 1021.
—— gum in, which yields xylose on saccharification, 1371.
—— influence of carbohydrates on the accumulation of asparagine in, 91.
—— occurrence of guanidine in, 908.
—— presence and function of phloroglucinol in, 1120.
—— respiration of, when injured under lessened oxygen tension, 1259.
—— sodium chloride in, 651.
Plasma and serum, 1113.
Platinic bromide and its compounds, heat of formation of, 3.
—— chloride, testing the purity of, 1526.
Platinoselenostannates, 282.
Platinothiocyanates, 286.
—— of the alkaloïds and amines, 287.
Platinous chloride, Trans., 445.
—— —— use of, as a source of chlorine, Trans., 445.
Platinum, absorption of oxygen by, 943.
—— iodonitro- and bromonitro-compounds of, 280.
—— lowering of the freezing point of bismuth by, Trans., 896.
—— lowering of the freezing point of cadmium by, Trans., 901.
—— lowering of the freezing point of lead by, Trans., 909.
—— nitrogen compounds of, 1283.
—— occlusion of hydrogen by, 567.
—— pure, preparation and assaying of, 789.
—— tetrachloride, anhydrous, Trans., 422.
—— thiocyanate, 286.
Platodipyridine bromide, 353.
—— chloride, 352.
Platosemipyridine chloride, 352.
Platosopyridine chloride, 352.
—— dibromide, 353.
Plessite from the Welland meteoric iron, 24.
Pneumonia, ptomaïne of, 1258.
Poisons, vegetable, influence of, on the germination of seeds, 228.
Polarisation, galvanic, at small electrodes, 759.
Pollen of *Pinus sylvestris*, 232.
Polydymite, 124.
Polymethylenes and naphthenes, 1310.
Polythionates, Proc., **1892**, 91.
Potassammonium, reaction of, on metals, 275.
Potassium acetate solutions, electrolysis of, Trans., 10.
—— amalgam, 275.

Potassium and thallium chlorates, solubility of mixed crystals of, 266.
—— bismuth chloride, 788.
—— bismuthate, 414.
—— bromide, action of sulphuric acid on, TRANS., 95, 101.
—— calcium thiosulphate, 12.
—— chlorate and iodine, interaction of, TRANS., 925.
—— chromosulphate, 784.
—— citrates, 149.
—— ferricyanide, estimation of, 526.
—— —— use of, in gasometry, 536.
—— —— volumetric analyses by means of, 1527.
—— ferrocyanide and ferricyanide, use of, in analysis, 1129.
—— —— volumetric analyses by means of, 1527.
—— fluoroxyhypovanadate, 787.
—— fluoroxyvanadate, 786.
—— hydrogen tartrate, use of, for titrating standard acids and alkalis, 525.
—— imidosulphonate, TRANS., 952.
—— iodide, estimation of iodates in, 657.
—— lead iodides and bromide, 780.
—— manganese chloride, 781.
—— manganites, hydrated, 569.
—— nitrosoplati-iodide, 281.
—— palladiochloronitrite, 1284.
—— permanganate solution, stability of, 1524.
—— phosphotungstates, 1160.
—— platibromonitrite, 1284.
—— platichloronitrite, 1284.
—— platidichloronitrite, 1284.
—— platinoselenostannate, 281.
—— platinothiocyanate, 286.
—— platinum thiostannate, reduction of, 944.
—— platipentachloronitrite, 1284.
—— platipentiodonitrite, 1284.
—— platitetrabromonitrite, 1284.
—— platitetriodonitrite, 281, 1284.
—— platitribromonitrite, 1284.
—— platitrichloronitrite, 1284.
—— platobromonitrite, 281, 1284.
—— platochloronitrite, 1283.
—— platodibromonitrite, 1284.
—— platodichloronitrite, 1284.
—— platodi-iodonitrite, 1284.
—— sodium hydrogen imidosulphonate nitrate, TRANS., 964.
—— spectroscopic detection and estimation of, 913.
—— stannochlorides, 785.
—— strontium thiosulphate, 13.
—— thioplatinosate, 944.
—— tricarballylates and their heats of formation, 762.
Potassium-nepheline, artificial formation of, 1286.
Potatoes, cooked, composition of, TRANS., 227.
Potential contact, differences of, 553.
—— differences of, at the surfaces of contact of very dilute solutions, 671.
Præsodymium, emission spectrum of, 2.
Precipitates, apparatus for washing, 1513.
Prehnitene, bromo-, action of sulphuric acid on, 968.
—— mono- and dichloro-, 967.
Pressure and specific volume of saturated vapours, 263.
—— influence of, on the expansion of water by heat, 1382.
—— of saturated water vapour, 396.
—— unequal, equilibrium of chemical systems under, 1148.
Propaldehyde, action of zinc and ethyl chloracetate on, 1300.
—— condensation of, with aniline, 1191.
—— dibrom-, 809.
Propaldehydeaniline, 1191.
Propane, 1 : 3-dinitro-, 1061, 1415.
—— nitrotribromo-, 1064.
—— sodiodinitro-, 1061.
—— tetrabromodinitro-, 1062.
Propaneparadisazoanisoïl, dinitro-, 1062.
Propanedisazobenzene, dinitro-, 1062.
Propanedisazotoluene, dinitro-, 1062.
Propargylamine, derivatives of, 30.
Propargyldithiocarbamic acid, 30.
Propargylic acid diiodide, 431.
Propargylphenylcarbamide, 31.
Propenyldimethylapionol, 1315.
Propenylparadibromobenzoic acid, para-, 605.
Propenylparahomosalicenylazoxime-ω-carboxylic acid, 319.
Propiomesitylene, action of hydroxylamine hydrochloride on, 314.
Propionamide, α-diiodo-, 452.
Propionamidine nitrate, 951.
—— nitrite, 53.
Propionates, metallic, 140.
Propionic acid, α-amido-, 1336.
—— —— β-iodo-, action of, on ethyl thiocarbamate, 440.
—— acids, β-oximido-, configuration of, 1069.
Propionohydroxamic acid, 699.
Propionyldiorthotolylhydrazine, 843.
Propionyldiparatolylhydrazine, 844.
Propionyldiphenylhydrazine, 843.
Propionylorthotolylhydrazine, 843.
Propionylparatolylhydrazine, 844.
Propionylpropionic acid and its dioximes, 351.
Propoxybenzamide, 595

Propoxybenzonitrile, 595.
Propyl alcohol, action of bromine on, 809.
—— —— vapour tension of, 397.
—— benzenesulphonate, 1220.
—— benzoate, γ-amido-, 213.
—— chlorides, chlorination of, 1414.
—— formate, magnetism of, 672.
—— hexyl ketone, 35.
—— phenyl ether, γ-chloro-, 717.
Propylacridine, 343.
Propylamidoacetic acid, 804.
Propylaminenitrobenzamide, γ-bromo-, 14.
Propylamines and their derivatives, 804.
Propylazobenzene, nitro-, 575.
Propylbenzamide, γ-bromo-, 212.
—— γ-chloro-, 213.
Propylbenzophenone, para-, 488.
—— —— oximes of, 489.
Propylcarbamide, 1421.
—— dibromo-, 30, 578.
Propylcinnamylamide, β-bromo-, 215.
—— γ-bromo-, 215.
Propyldithiobiuret, α-, 704.
Propylene bromide, action of, on the sodium derivatives of ethyl acetoacetate and ethyl benzoylacetate, Trans., 67.
—— dibromo-, 420.
—— nitro-, 575, 1062.
—— nitrobromo-, 1064.
—— sodionitro-, 1062.
Propyleneazobenzene, nitro-, 1063.
Propyleneazometabromobenzene, nitro-, 1064.
Propyleneazopseudocumene, nitro-, 1064.
Propylenecarbamide, bromo-, 578.
Propyleneglycol, diacetin of, 1163.
Propylenemetazobenzoïc acid, nitro-, 1064.
Propyleneorthazotoluene, nitro-, 1063.
Propyleneparazoanisoïl, 1064.
Propyleneparazophenetoïl, nitro-, 1064.
Propyleneparazotoluene, nitro-, 1063.
Propyl-group, intramolecular change of the, 43.
Propylidenaniline, 1191.
Propylisoformanilide, 708.
Propylisosuccinimide, 701.
Propylmetanitrobenzamide, β-bromo-, 213.
Propyl-α-naphthylamine, 1338.
Propyl-β-naphthylamine, 1338.
Propyloxamic acid, 804.
Propylparisopropyltoluene, ortho-, 985.
Propylpentenethiocarbamide, symmetrical, 702.
Propylphenylacetamide, β-bromo-, 214.
—— γ-bromo-, 215.
Propylphthalimide, 157.
Propylsuccinimide, 701.
Propyltricarballylic acid, 42.
Propyltrimethylammonium salts, 949.
—— —— bromo-, 950.
Proteïd, new, from human blood serum, 224.
Proteïds, calorific values of, 4.
—— colour reactions of, 1036.
—— in green and etiolated leaves, 520.
—— of maize, 379, 746, 749.
—— of the oat kernel, 1120.
Protocotoïn, 62.
—— action of potash and methyl alcohol on, 873.
—— derivatives of, 63, 874.
Protoplasm, new albumin from, 86.
Prussic acid poisoning, antidote for, 1019.
Pseudocumene, fluoro-, 968.
Pseudocumylparatolylcarbamide, 979.
Pseudonicotine oxide, 1010.
Pseudopelletierine, 1110.
Pseudosolution, Trans., 148.
Pseudothiocyanogen, properties of, 292.
Pseudotropine, 1366.
Ptomaïnes of infectious diseases, 1258.
Puleone, an isomeride of camphor, 627.
Puleonoxime, 627.
Pump, Sprengel, automatic replacement of mercury in, 8.
Pupin, 1501.
Putrefaction of bile, 518.
—— of milk, 1116.
Pyrazole-derivatives, 731.
—— —— formation of, from the dichlorhydrins and tribromhydrin, 884.
Pyrazoles, platinum compounds derived from, 885.
Pyrazolone-derivatives, constitution of, 145.
—— —— synthesis of, 634.
Pyrazolones, nomenclature of, 1004.
Pyrethrosin, 349.
Pyridine, action of chloromethyl alcohol on, 504.
—— carbonyl bromoplatinite, 352.
—— chloriodide, 1356.
—— α-chloro-, 209.
—— chloroplatinite, 352.
—— constitution of, 210.
—— hydrogen diaminechromium thiocyanate, 1001.
—— platinothiocyanate, 287.
Pyridine-bases, action of, on sulphites, 1103.
—— —— of the β-series, 628.
Pyridinebetaïne, preparation of, 1433.
Pyridinecarboxylic acids from berberine, 1357.

Pyridine-derivatives, preparation of, from the lactone of triacetic acid, TRANS., 721.
Pyridine-like bases in petroleum, 1357.
Pyridone, α-, 208.
Pyridylacrylic acid, 77.
Pyridylbromopropionic acid hydrobromide, β-, 77.
Pyridyldibromopropionic acid, 77.
Pyridylethylene, 77.
Pyridyllactic acid, α-, 76.
Pyridyllactic acid, β-, 78.
Pyridyl-ω-trichloro-α-hydroxypropane, 75.
Pyridyl-α-trichloropropylene, 76.
Pyrites, burnt, utilisation of, in the preparation of iron salts, 1281.
Pyrocinchonic anhydride, preparation of, 814.
Pyrogallaurin, 1470.
Pyrogallol, constitution of, 1446.
—— conversion of gallic acid into, 1314.
—— derivatives of, 715.
—— sodium derivatives of, 1313.
—— thermochemistry of, 764.
Pyromucamide, thio-, 831.
Pyrophenite from Harstigen mine, Sweden, 1412.
Pyrotartaric acid, normal, thermochemistry of, 1141.
Pyroxene, analyses of, 1409.
Pyroxene-family, 1408.
Pyroxenic rock, azure blue, from New Mexico, 1057.
Pyrrodiazole, 637.
Pyrrodiazolecarboxylic acid, 636.
Pyrrolidine, synthesis of, 131.
Pyrroline, determination of the constitution of homologues of, 74.
Pyruvic acid, condensation of, with dicarboxylic acids, 814.
—— —— dibromo-, action of hydroxylamine on, 815.
—— —— hydrazones, TRANS., 786.
—— —— magnetic rotation of, TRANS., 807, 836.
—— —— thiophenylhydrazine, 1326.
—— anilide and its hydrazone, 1440.
—— —— imidochloride, 1440.
—— orthotoluidide, 1441.

Q.

Quartz, 1055.
Quercitol, thermochemistry of, 764.
Quinaldine, β-chloro-, synthesis of, 505.
—— synthesis of, 1245.
Quinamyline, 1253.
Quinazolines, 217.
—— thio-, new synthesis of, 1495.
Quince-juice, a sugar from, 128.
Quinidine benzyl salts, 1250.
—— compounds of, with hydriodic acid, 83, 640.
—— diethiodide, 1250.
—— diethyl salts, 1250.
—— dimethiodide, 1250.
—— ethiodide, 1249.
—— ethobromide, 1249.
—— hydriodo- and its salts, 1364.
—— methiodide, 1249.
Quinindole-α-carboxylic acid, ana-, TRANS., 787.
Quinine, action of hydriodic acid on, 81, 83, 640.
—— behaviour of, with methyl iodide, 221, 892.
—— compounds of, with hydriodic acid, 83, 640.
—— conversion of cupreïne into, 1010.
—— detection of, in urine, 665.
—— dibromide, 1012.
—— dimethiodide, 1363.
—— homologues of, 1253.
—— hydrochlorides, 514.
—— hydrogen diaminechromium thiocyanate, 1001.
—— methiodides, 1363.
—— preparation of homologues of, 222.
—— salts, appearance of fluorescence in, TRANS., 789.
Quininesulphonic acid, 515.
Quinisopropyline, 1253.
Quinitol, 833.
Quinol, chlorotribromo-, TRANS., 592.
—— compound of, with phenylhydrazine, 49.
—— diisoamyl ether, 1444.
—— metachlorobromo-, TRANS., 562.
—— metadibromo-, TRANS., 562.
—— metadichlorobromo-, TRANS., 567.
—— metadichlorodibromo-, TRANS., 579.
—— paradichlorobromo-, TRANS., 565.
—— sodium compounds of, 1184, 1185.
—— thermochemistry of, 764.
—— trichlorobromo-, TRANS., 593.
—— trinitro-, derivatives of, 314.
Quinoline alkyl iodides, action of alkalis on, 878.
—— γ-amido-, 725.
—— ana-amido-, TRANS., 785.
—— γ-bromo-, 630, 875.
—— chloriodide, 1357.
—— ethiodide, oxidation of, 730.
—— hydrogen diaminechromium thiocyanate, 1001.
—— methyl hydroxide, oxidation of, 729.
—— nitration of, TRANS., 782.
Quinoline-derivatives, appearance of colour in, TRANS., 789.

Quinoline-derivatives, synthesis of, by means of alkyl acetoacetates, 78.
Quinoline-group, attempted synthesis of a nitramine of, 725.
Quinolinehydrazine, ana-, TRANS., 784.
Quinolinehydrazines, 212.
Quinolinemethylium alkyl oxides, nitro-bromo-, 881.
—— hydroxide, bromo- and nitro-derivatives of, 880, 881.
Quinolinemethylpyrazolone, ana-, 788.
Quinoline-α-phenylsulphonic acids, 1003.
Quinolines, amido-, 1488.
—— hydrazines of, TRANS., 782.
Quinolinesemicarbazide, ana-, TRANS., 786.
Quinoline-series, ketones of the, 1488.
—— —— quaternary ammonium bases of, 1358.
Quinolmetachlorobromo-, chlorination of, TRANS., 578.
Quinone, action of ethyl acetoacetate on, 608.
—— and its derivatives, physiological action of, 1115.
—— chlorotribromo-, TRANS., 590.
—— halogen derivatives of, TRANS., 558, 589.
—— isomeric change in the halogen derivatives of, TRANS., 558.
—— metachlorobromo-, TRANS., 562.
—— metadibromo-, TRANS., 561.
—— metadichloro-, TRANS., 559.
—— —— bromination of, TRANS., 576, 580.
—— metadichlorobromo-, TRANS., 566.
—— metadichlorodibromo-, TRANS., 578.
—— paradichloro-, TRANS., 558.
—— —— bromination of, TRANS , 572.
—— paradichlorobromo-, TRANS., 563.
—— paradichlorodibromo-, TRANS., 572.
—— trichlorobromo-, TRANS., 592.
Quinonehæmatin, 1115.
Quinoneoxime acetate, 1457.
—— benzoate, 1457.
—— benzoxide, 1457.
—— ethers, 1456.
—— ethoxide, 1457.
—— methoxide, 1456.
Quinones, action of bleaching powder and of hypochlorous acid on, 720, 859, 970.
Quinonimides, formation of, from amidoazo-compounds, 1476.
Quinopropyline, 1253.
Quinoxazines, 887.
Quinoxazones, 887.

R.

Rabbits, hydrophobic, catechol in the urine of, 1115.
Racemic acid solutions, sp. gr. of, 964.
Radicles, substituted alcohol, directly united with carbon or with nitrogen, characteristic difference between, 106.
Radish, cooked, composition of, TRANS., 227.
—— quantity of starch in the tubercles of the, 92.
Raffinose, estimation of, in vegetable products, 249.
—— precipitation of, by ammoniacal lead acetate, 1294.
—— preparation of, from molasses, 422.
Rain as a source of nitrogen for vegetation, 233.
—— water, ammonia in, 381, 909.
Ramie plant, composition of, 1511.
Reaction, velocity of. See Velocity.
Realgar, analysis of, 657.
—— from the Yellowstone National Park, 283.
Rectorite, 22.
Refraction and dispersion of sodium chlorate, 1.
—— molecular, of nitrogen compounds, 933.
—— —— of solid chemical compounds in their solutions, 929.
—— —— of sulphines, 34.
Refractive index, density, molecular weight, and diathermanous power of a substance, relation between, 1.
—— indices and compressibility of liquids, relations between, 669.
—— —— of saline solutions, 929.
—— power of certain organic compounds at different temperatures, TRANS., 287.
—— powers of isocyanides and nitriles, 757.
Resazurin, formula of, 164.
Resin, detection of, in bees'-wax, 923.
—— of *Pinus abies*, terpenes from, 625.
—— oil, detection of, in terebenthene, 923.
Resins from *Pinus laricio* and *Picea vulgaris*, 204.
—— natural, 204.
—— of *Ficus rubiginosa* and *F. macrophylla*, TRANS., 916.
Resorcenylamidoxime, β-, 317.
Resorcinol diethyl ether, action of nitrous acid on, 44.
—— —— —— nitroso-, 45.
—— ethyl ether, nitroso-, 44.
—— heptachloro-, compounds derived from the so-called, 1186.
—— sodium compounds of, 1184, 1185.

Resorcinol, tetrachloro-, 1462.
—— thermochemistry of, 764.
Resorcinol-blue, Weselsky's, synthesis of, 163.
Resorcinoldisazobenzene, 977.
—— symmetrical, 977.
Resorcinyl orthacetate, 309.
Resorcylaldoxime, β-, 317.
Resorcyldialdoxime, 317.
Resorcylonitrile, β- 317.
Respiration, air vitiated by, 1502.
—— apparatus, 1257.
—— of plants under lessened oxygen tension and when injured, 1259.
Respiratory value of hæmocyanin, 1370.
Retiform tissue, 1113.
Retinite, 573.
Rhamnolactone, polarisation phenomena of, 1341.
Rhamnonic acid, polarisation phenomena of, 1431.
Rhamnose from frangulin, TRANS., 7.
—— multirotation of, 1420.
—— thermochemistry of, 763.
Rhamnus prushiana, cascarin from, 1483.
Rhodeochromium salts, 782.
Rhodinaldehyde, 203.
Rhodinol, 203, 625.
Rhodinolic acid, 203.
Rhodium-bases, constitution of, 783.
Rhodosochromium salts, 782.
Rhyolites, minerals in hollow spherulites of, 23.
Ribonic acid, 438.
Ribose and its derivatives, 439.
Rice, effect of excessive liming on the growth of, 94.
Ricinelaïdic acid, oxidation of, 1304.
Ricinoleïc acid, oxidation of, 1304.
Riebeckite from Michigan, 793.
Rings, closed, hydrogenation of, 1040.
—— —— nomenclature of, PROC., 1892, 127.
Rock of the Jiwaara, in Finland, 1058.
Rocks, acid, reproduction of, 23.
Rock-salt from Torda and from Vizakna, 1054.
Rosaniline, formation of, 340.
Rose oil, German and Turkish, 203, 625.
Rosin, estimation of, in its mixtures with fatty acids, 389, 546.
—— oil, detection of, in fatty and mineral oils, 548.
Rotation, magnetic, of dissolved salts, PROC., 1892, 12.
Rotatory power, laws of, and stereochemistry, 758, 759.
—— —— of diacetyltartaric-derivatives, 669.
Rubbadin, 1076.
—— action of nitric acid on, 1077.
Rubbadin, action of sulphuric acid on, 1077.
Rubidium antimony chlorides, 788.
—— bismuth chlorides, 789.
—— compounds, extraction of, from carnallite, 1395.
—— manganese chloride, 781.
Rubidium-carnallite, 1395.
Ruby from Burma, 1055.
Rumpfite, from Upper Styria, 417.
Ruthenium chloride, 688.
—— hydroxychloride, 688.
—— oxides, saline compounds of the lower with the higher, 282.
—— peroxide, action of light on, 282.

S.

Sabella, ash of the blood of, 1256.
Saccharin, specific rotatory power of, 1421.
—— thermochemistry of, 763.
Safrole, oxidation products of, 46, 310.
Salicylaldehyde, action of acetic chloride on chloro-, bromo-, and nitro-derivatives of, 1458.
—— ethylation of, 57.
—— reduction of, by zinc-dust and acetic acid, 168.
Salicyldiureïde, action of ethyl acetoacetate on, 56.
Salicylic acid, action of heat on, 1208.
—— —— compound of, with phenylhydrazone, 49.
—— —— condensation of nitrobenzaldehydes with, 621.
—— —— separation of, from benzoic acid, 1532.
Saline hydrates, formation of, at high temperatures, 119.
Salsify, cooked, composition of, TRANS., 227.
Salt, solution of a, in an indifferent salt solution and of a gas, analogies between, 397.
—— solutions, aqueous, viscosity of, 1044.
—— —— boiling, determination of the temperature of the steam arising from, TRANS., 495.
—— —— compressibility of, 766.
—— —— electrical behaviour of metals in, 393.
Salts, capillary constants of, at their melting points, 7.
—— changes of volume in solutions of, 766.
—— coloured, absorbent power of, and electrolytic dissociation, 757.
—— determination of the electrolytic

dissociation of, by means of solubility experiments, 1143.
Salts, dissolved, magnetic rotation of, Proc., **1892**, 12.
—— double, solubility of, 1145.
—— ethereal, normal isomeric, of the fatty series, calculation of the boiling points of, 260.
—— formation of layers in solutions of, in mixtures of water and organic liquids, 1146.
—— heat of dissolution of, in water, 676.
—— heat of formation of, in alcoholic solution, 262.
—— metallic, electromotive forces of, 255.
—— —— organic liquids as solvents for, 558.
—— mutual solubility of, in water, 8, 264.
—— solubility curves of pairs of, 1384.
—— state of, in solution, 397.
Samarium, spectra of, 780.
Samarskite from Colorado, 416.
Sand, siliceous, of Monte Soratte, 23.
Sandal wood, essence of, adulteration of, 1379.
Sandmeyer's reaction, use of sodium hypophosphite in, 305.
Santinic acid, 871.
Santonic acid, 1352.
—— —— oxidation of, 1353.
—— —— oxime of, 1352.
Santonin, derivatives of, 869.
Santoninamine, 869.
Santonine, detection and estimation of, 666.
Saponification by sodium ethoxide, 139.
Saponins, 350.
Sapotin, 724.
Sapotiretin, 725.
Sapotoxin from *Agrostemma githago*, 350.
Scarlet runners, cooked, composition of, Trans., 227.
Schiff's bases, 1189.
Scopolamine, 1255, 1366, 1498
Sea-kale, cooked, composition of, Trans., 227.
Sebacamide, 1180.
Sebacic acid, derivatives of, 1180.
Seeds, influence of vegetable poisons on the germination of, 228.
Selenium, allotropic states of, 405.
Semithiocarbazides, di-substituted, Trans., 1012.
Sepia officinalis, blood of, 648.
Serpentine rock from Borzanasca, 1058.
Serum and plasma, 1113.
—— human blood, new proteïd from, 224.
Serum, toxicity of 228.
Sesame oil, detection of, in olive oil, 1133.
Silicates, action of ammonium chloride at its dissociation temperature on, 772.
—— fractional analysis of, 945.
Silicic acid, colloïdal solutions of, Trans., 154.
—— —— estimation of, in fluorides, 1127, 1128.
Silicon carbide, 1050.
—— compounds, Trans., 453.
—— condition of, in cast iron, 19.
—— estimation of, in aluminium, 1130.
—— graphitoïdal, reducing action of, 115.
—— tetrachloride, action of, on substituted phenylamines, Trans., 453.
—— —— reactions of, 1273.
—— thiochloride, 404.
Silk, nitrated, 1111.
—— rotatory power of, 254, 645.
—— specific gravity of, 1036.
—— tissue, detection of vegetable fibre in, 667.
Silver, absorption of oxygen by, 943.
—— acetate, action of iodine on, 1301.
—— —— dry distillation of, 37.
—— acetylide, 1416; Proc., **1892**, 109.
—— action of chlorine and of bromine on, 118.
—— action of nitric acid on, 1403.
—— allotropic, 15, 116, 405.
—— and lead, separation of, 1522.
—— barium phosphotungstate, 1160.
—— blue, 15.
—— caproate, action of iodine on, 1301.
—— chloride, action of light on, 775; Trans., 728.
—— —— solution of, in aqueous ammonia, 1154.
—— colloïdal, 117, 941.
—— —— pure, preparation of, 775.
—— electrolytic detection of, 541.
—— electrolytic separation of, from osmium, 920.
—— estimation of, by means of hydroxylamine hydrochloride, 662.
—— estimation of small quantities of, in base metals, 1525.
—— hydrosulphide, Trans., 132.
—— imidosulphonates, Trans., 974.
—— lowering of the freezing point of bismuth by, Trans., 895.
—— lowering of the freezing point of cadmium by, Trans., 900.
—— lowering of the freezing point of lead by, Trans., 907.

Silver nitride, 112.
—— nitrosilicate, 684.
—— ore, new, 1404.
—— organosol of, 775.
—— permanganate, decomposition of, 942.
—— permolybdate, 1160.
—— phenylacetylide, 831.
—— salts, compounds of thiourea with, TRANS., 249.
—— —— of fatty acids, dry distillation of, 38, 293, 811.
—— —— organic, dry distillation of, 293.
—— slags, estimation of bismuth in, 919.
—— sulphite, 684.
—— zinc, and lead, separation of, in galena and blende, 1378.
Silver-cadmium alloy, analysis of, TRANS., 913.
Sinapanpropionic acid, 441.
Siphon for hot liquids or for those evolving gases or vapours, 270.
Slag, estimation of, in wrought iron, TRANS., 551.
Slags, estimation of phosphoric acid in, 382.
—— silver, estimation of bismuth in, 919.
Soap analysis, 550.
—— estimation of combined alkali in, 384.
Sodammonium, action of, on metals, 275, 773.
Sodium, action of, on chromic fluoride, 19.
—— alloys of, 773.
—— amalgam, 275.
—— ammonium imidosulphonate, TRANS., 961.
—— and tin, alloy of, 572.
—— as a plant food, 1508.
—— bromide, action of sulphuric acid on, TRANS., 101, 102.
—— carbonate and sodium hydrogen carbonate, solubility of, in solutions of sodium chloride, 116.
—— chlorate, refraction and dispersion of, 1.
—— chloride, cryoscopy of dilute solutions of, 1045.
—— —— in plants, 651.
—— —— influence of, on nitrogenous excretion, 904.
—— —— measurement of the vapour pressures of solutions of, TRANS., 773.
—— citrates, 149.
—— ethoxide, saponification by, 139.
—— ethylthiosulphate, preparation and properties of, 799.
Sodium ferrinitrosonaphtholsulphonate, 346.
—— ferrite, hydrated, dehydrating action of glycerol on, 119.
—— fluoroxyvanadate, 786.
—— hydrogen sulphide, action of iodine on, 681.
—— hypophosphite, use of, in Sandmeyer's reaction, 305.
—— imidosulphonates, TRANS., 954.
—— isopropoxide, 691.
—— —— thermochemistry of, 674.
—— lowering of the freezing point of bismuth when alloyed with, TRANS., 892.
—— lowering of the freezing point of cadmium by, TRANS., 897.
—— lowering of the freezing point of lead by, TRANS., 904.
—— nitride, 112.
—— nitrite, analysis of, 1029.
—— permolybdate, 1160.
—— platinoselenostannate, 282.
—— separation of, from mercury and phosphoric and arsenic acids, 530.
—— stannibromide, 121.
—— sulphate, action of carbon on, in presence of silica, 565.
—— —— boiling point of a solution of, PROC., **1892**, 94.
—— —— solubility of, 398.
—— thiosulphate, change proceeding in an acidified solution of, where the products of change are retained in the system, TRANS., 176.
Soil, absorption of oxyhydrogen gas by, 377.
—— arable, kaolin in, 1026.
—— estimation of phosphoric acid in, 750.
—— influence of, on the assimilation of free nitrogen by plants, 372.
—— influence of the nature of, on vegetation, 1121.
—— inoculation, experiments on, 1512.
—— loss of nitrogen in the decomposition of nitrogenous matters in the, 374.
—— phosphoric acid in, 233, 750.
—— presence of boric acid in the products of, 93.
—— vegetable, estimation of sulphur in, and the forms in which it is present, 656.
—— —— spontaneous oxidation of, 655.
—— the phosphoric acid of, 233, 750.
Soils, action of lime on, 94.
—— arable, estimation of kaolin in, 1031.
—— —— fixation of atmospheric nitrogen by, 522.

Soils, fallow, influence of clay and organic nitrogen in, on the absorption of atmospheric nitrogen, the retention of nitrogen, and nitrification, 656.
—— inorganic substances in, 1513.
Solanaceæ, alkaloïds of, 231.
Solanum nigrum, alkaloïds of, 232.
—— *tuberosum*, alkaloïds of, 232.
Solubility curve, theory of the, 559.
—— curves of pairs of salts, 1384.
—— mutual, of salts in water, 8, 264.
—— of double compounds, 1047, 1385.
—— of double salts, 1145.
—— of gases in water, 107, 271.
—— of mixed crystals, 265, 560.
Solution, alteration of the conductivity of, by addition of a non-electrolyte, 1382.
—— and pseudo-solution, Trans., 148.
—— and suspension, connection between, Trans., 151, 165.
—— law of thermodynamical coincidence and its application to the theory of, 557.
—— nature of, 108.
—— passage of substances in, through mineral filters and capillary tubes, 1267.
—— state of salts in, 397.
—— the new theories of, 264.
—— theory of residual chemical affinity as an explanation of the physical nature of, 559.
Solutions, a new property of certain, Trans., 160.
—— application of thermodynamics to, 395.
—— aqueous, action at a distance of water vapour on, 936.
—— —— diffusion in, 1265.
—— —— salt, viscosity of, 1044.
—— —— specific gravities of, 765.
—— cane-sugar, cryoscopy of, 109, 678, 1046.
—— chemical equilibrium in, 1146.
—— colloïdal, nature of, 766.
—— —— pedetic motion in relation to, Proc., 1892, 17.
—— dilute, applications of gaseous laws to, 935.
—— —— cryoscopic behaviour of, 8, 678, 1045.
—— —— existence of acid or basic salts of monobasic acids in, 110.
—— —— of cane sugar, freezing points of, 678, 1046.
—— isohydric and non-isohydric, of acids, velocity of reaction in mixtures of, 936.
—— measurement of the osmotic pressure of, 556.
Solutions, measurement of the vapour pressures of, Trans., 769.
—— molecular refraction of, 929.
—— of a gas and of a salt in an indifferent salt solution, analogies between, 397.
—— of salts, changes of volume in, 766.
—— —— in mixtures of water and organic liquids, formation of layers in, 1146.
—— of some metallic chlorides, physical properties of, Trans., 339.
—— partially miscible, 1046.
—— saline, compressibility of, 766.
—— —— refractive indices of, 929.
—— —— temperature of steam arising from, Trans., 495.
—— saturated, 1047.
—— stochiometry of, 1382.
—— strong, and the dissociation hypothesis, 108.
—— sugar, sp. gr. of, 935.
—— theory of, 1045.
—— very dilute, determination of the freezing points of, 935.
—— —— —— potential differences at the surface of contact of, 671.
Solvents, behaviour of optically active substances in mixtures of two, 1137.
Sorbinose, thermochemistry of, 763.
Sorbitol, compounds of, with molybdic acid, 422.
—— occurrence of, in the fruit of the cherry laurel, 908.
Sparteïne, 1362.
Specific gravities of aqueous solutions, 765.
—— gravity of gases, determination of, 1267.
—— —— of sugar solutions, 935.
—— —— relation of E.M.F. to, 257.
Specific heat of aluminium, 673.
—— —— of liquids at temperatures above the boiling point, 761.
—— —— of the diamond, 761.
—— heats of liquids, calculation of, 2.
Specific inductive capacity, relation of, to latent heat of evaporation, 258.
Specific rotatory power of galactonic acid and galactonolactone, 1432.
—— —— —— of gluconic acid and gluconolactone, 1432.
—— —— —— of invert sugar and of dextrose obtained from cane sugar by means of invertase, Trans., 408.
—— —— —— of rhamnonic acid and rhamnolactone, 1431.
—— —— —— of rhamnose and the saccharins, 1420.
—— —— —— of tartaric acid and its salts, 1308.
—— —— —— of xylose, 1420.

Specific volume and pressure of saturated vapours, 263.
Spectra, absorption, of thin metallic films, 1037.
—— emission, of neodymium and præsodymium oxides and of luminous solids containing neodymium, 2.
—— of samarium, 780.
Spectroscopic detection and estimation of potassium, 913.
Spectrum, absorption, of hæmatin, sensitiveness of, 1369.
—— of gallium, 930.
—— of hydrogen, Hasselberg's second or compound, 1381.
Spermine, supposed reaction of, 1300.
Spessartine from Virginia, 1411.
Spinach, cooked, composition of, TRANS., 227.
Spirits, analysis of, 387.
—— estimation of fusel oil in, 543.
—— examination of, for secondary constituents, 244.
—— of wine, detection of higher alcohols in, 1379.
Spring, hot mineral, at Finca Huracato, Salta, Argentine Republic, 574.
Stannibromides, 121.
Stannic acid, α-ortho-, 412.
Starch, colloïdal solutions of, TRANS., 156.
—— combination of iodine with, 801.
—— conversion of, into amyl alcohol by a bacterium, 90.
—— digestion of, by dogs, 516.
—— fixation of iodine by, 578.
—— in the fungus *Boletus pachypus*, 230.
—— iodide of, 578, 801, 1171.
—— product of the oxidation of, 1171.
—— quantity of, in the tubercles of the radish, 92.
—— thermochemistry of, 764.
Steam arising from boiling salt solutions, temperature of, TRANS., 495.
Stearic acid, action of bromine on, 695.
Stearolic acid, diiodo-, 470.
—— phenylhydrazide, 1428.
Steel, direct estimation of aluminium in, 102.
—— estimation of carbon in, 913.
—— estimation of chromium in, 538.
—— estimation of manganese in, 916, 1030.
—— estimation of nitrogen in, 237.
—— estimation of phosphorus in, 528, 529, 911.
—— estimation of sulphur in, 382.
—— estimation of tungsten in, 539.
Stereochemical models of organic molecules, 679.
Stereochemistry and the laws of rotatory power, 758, 759.
—— and the oximes, 50.
—— of diacetyltartaric acid, 758, 759.
Stilbene, formation of, from the polymeric thiobenzaldehyde, 184.
—— paradinitrorthodichloro-, 444.
—— substitution products of, 718.
Stilbene-series, isomeric change in, 1224.
Stomach, estimation of free hydrochloric acid in the, 236, 1125.
Stomach-contents, estimation of peptones in, 1136.
Straw, aërobic nitrate-reducing ferment in, 1259.
Stromeyerite from California, 1407.
Strontium and calcium, separation of, 915.
—— —— separation of, as chromates, 914.
—— barium, and calcium, separation of, 660.
—— carbonate, action of potassium sulphate on, 1276.
—— chloride, solubility of, 398.
—— chromate, solubility of, in dilute alcohol, 914.
—— nitride, 566, 776.
—— phosphates, 1156.
—— potassium thiosulphate, 13.
—— salts, physiological action of, 227.
—— —— pure, preparation of, 1277.
—— —— removal of barium from, 776.
—— tartrate, behaviour of, with plastered wines, 93.
—— volumetric estimation of, 1521.
Strychnine, 1012.
—— hydrogen diaminechromium thiocyanate, 1001.
Suberic acid, thermochemistry of, 1041.
Substitution in the fatty series, 577, 1414.
Succinamide, asymmetrical diiodo-, 453.
Succinendiamidoxime, formation of, 137.
Succinic acid, action of hydroxylamine on derivatives of, 136.
—— —— amido- and anilido-derivatives of, 819.
—— —— separation of malic acid from, 1531.
—— —— thermochemistry of, 1041.
—— diamide, imido-, 820.
Succinimidine nitrite, 53.
Succinimidoxime, 136.
Succinylphenylhydrazide, β-, 1494.
Succus entericus, human, 1368.
Sugar, analysis of, 388.
—— cane-, freezing points of dilute solutions of, 678, 1046.

Sugar, cane-, invert sugar and dextrose or levulose, examination of mixtures of, 248.
—— —— solutions, cryoscopy of, 109, 678, 1046.
—— —— sp. rot. power of, in dilute solution, 801.
—— —— thermochemistry of, 764.
—— disappearance of, from the blood, 363.
—— formation of, from peptones in blood, 1502.
—— formation of, in the organism, 1113.
—— formation of, in the organism when oxygen is deficient, 362.
—— from linseed, 1293.
—— from quince juice, 128.
—— in blood, 743.
—— invert, specific rotatory power and cupric reducing power of, Trans., 408.
—— milk-, behaviour of, in a diabetic 903.
—— —— thermochemistry of, 764.
—— potato-starch-, recognition of, in wine, 922.
—— products, estimation of calcium salts in, 1377.
—— solutions, sp. gr. of, 935.
Sugar-cane, healthy and diseased, analyses of, 1372.
Sugars, aromatic, 1447.
—— change of, in the alimentary canal, 902.
—— disappearance of the multirotation of, in ammoniacal solution, 1419.
—— distribution of, in *Boletus edulis* and *B. aurantiacus*, 519.
—— estimation of, by means of Ost's copper solution, 387.
—— richer in carbon from glucose, 1164.
—— thermochemistry of, 933.
Sulphanilic acid, transformation of, into sulphanilocarbamic acid in the animal economy, 903.
Sulphanilocarbamic acid, 904.
Sulphatammon, Trans., 949.
Sulphates, anhydrous, crystallised, 941.
—— from California, 1407.
—— metallic, efflorescence of, 1271.
—— volumetric estimation of, 1377.
Sulphide solutions, physical constitution of, Trans., 137.
Sulphides, inorganic, estimation of sulphur in, 657.
—— metallic, action of ferric chloride on, 18, 278.
—— soluble, volumetric estimation of, 1515.
Sulphines, molecular refraction and dissociation of solutions of, 34.
Sulphinic acids, tautomerism of, 623.
Sulphinic-derivatives and their analogies to compounds of organic amines, 34.
Sulphite and thiosulphate, action of iodine on a mixture of, Trans., 1083.
Sulphobenzaldehyde, bromo- and hydroxy-derivatives of, 337.
Sulphobenzamidinic acid, 714.
Sulphobenzoic acid, meta-, orthamido-, 333.
—— —— —— orthobromo-, 333.
—— —— —— paramido-, 332.
Sulphobenzoic acid, ortho-, nitro-, 479.
Sulphobutyric acid, β-, 424.
Sulphonal, physiological action of, 1507.
Sulphones, chemical and physiological relations of, 153.
Sulphonic acid, alkyl salts of, 1219.
—— acids, anhydrides of, Proc., **1892**, 41.
—— —— preparation of ethereal salts of, Proc., **1891**, 184.
—— chlorides, action of alcohol on, Proc., **1891**, 184.
Sulphur, action of, on metallic solutions, 770.
—— action of, on the alkaline earths, 770.
—— action of, on the alkalis, 770.
—— action of, on water at 100°, 770.
—— and phosphorus, compounds of, 14.
—— allotropic states of, 405.
—— combustion of, in oxygen, 679.
—— estimation of, 382, 1375.
—— estimation of, in galena, 658.
—— estimation of, in inorganic sulphides, 657.
—— estimation of, in organic substances, 382.
—— estimation of, in red copper, 753.
—— estimation of, in vegetable soil, 656.
—— flowers of, action of sulphurous acid on, Trans., 199.
—— forms in which present in vegetable soils, 656.
—— from the Yellowstone National Park, 283.
—— in iron, estimation of, 1376.
—— in steel and iron, estimation of, 382.
—— insoluble, 1389.
—— plastic, formation of, from sulphur vapour, 1150.
—— tetroxide, 111.
Sulphuric acid, amides and imides of, 1389.
—— —— and water, contraction on mixing, 271.
—— —— combined, estimation of, 104, 538.

Sulphuric acid, combined, volumetric estimation of, 1515.
—— —— cryoscopic behaviour of weak solutions of, 678.
—— —— dilute, density and composition of, 271.
—— —— estimation of, 659.
—— —— formation of, in burning coal-gas, 1151, 1374, 1389.
—— —— in urine, volumetric estimation of, 1377.
—— —— solutions, densities of, 271, 272.
Sulphurous acid, action of, on flowers of sulphur, TRANS., 199.
—— —— complex salts of, 564.
—— —— constitution of, 1324.
—— anhydride, decomposition of, by carbon at high temperatures, 681.
—— —— microscopic detection of, 237.
Sulphuryl holoxide, 401.
Superphosphates, analysis of, 1125.
Supersaturation, 398.
Suspension and solution, connection between, TRANS., 151, 165.
Syrup, estimation of calcium salts in, 1377.

T.

Tænite from the Welland meteoric iron, 24.
Talomucic acid, 299.
Talonic acid, 299.
Talose, 299.
Tannic acid, physiological action of, 905.
Tannin analysis, Lowenthal's method of, 667.
—— derivatives of, 181.
—— estimation of, 1135.
—— estimation of, in barks, 390.
—— from chestnut wood, 716.
Tariric acid, 582.
Tartar, estimation of, in sweet wines, 1531.
Tartaric acid and its salts, specific rotatory power of, 1308.
—— —— detection of, in citric acid, 546.
—— —— separation of malic acid from, 1531.
—— —— solutions, sp. gr. of, 964.
—— —— synthesis of, 822.
—— diphenylhydrazide, action of carbonyl chloride on, 511.
Tartarotartaric acid, 965.
Tartranilide, acetyl derivatives of, 54.
—— preparation of, 54.
Tartrates, dissociation in dilute solutions of, 588, 1144.
Tartromalic acid, 589.
Tartronic acid, alkali salts of, 675.
—— —— thermochemistry of, 675.
Tea, analysis of, 926.
Teak, mineral substances in, 230.
Teas, preparation of, 1371.
Teeth, influence of various salts on the composition of, 647.
Tellurium from Faczebaya, 1054.
Temperature and solubility, law of the connection between, 559.
—— change of the empirical and theoretical isothermals of mixtures of two substances with the, 259.
—— influence of, on the refractive power of certain organic compounds, TRANS., 287.
—— volume and E.M.F., changes of, on mixing electrolytes, 930.
Temperatures, critical, of mixed liquids, 262.
—— high, optical measurement of, 761.
—— of saturated vapours of various liquids under the same pressure, 1143.
—— very low, physical and chemical phenomena at, 1138.
Tension, maximum, with which hydrogen is set free from solutions by metals, 561.
Teraconic acid, synthesis of, 427.
Terbium earth, 1400.
Terebenthene, 624, 625.
—— detection of resin oil in, 923.
Terecamphene, 624, 635.
Terfâs, relation between truffles and, 654.
Terfezia bouderi, analysis of, 654.
—— *claveryi*, analysis of, 654.
—— *hafazi*, analysis of, 654.
Terpene, dextro-, from Russian turpentine, degree of saturation of, 1350.
Terpenes and their derivatives, 200, 347, 623, 625, 722, 1100.
—— from the resin of *Pinus abies*, 625.
Terpin hydrate, action of hydriodic acid on, 867.
—— —— from eucalyptus oil, 1235.
Terpinol hydrate, reduction of, 1351.
Tetrabenzoyloxamide, 1084.
Tetrabenzylcarbamide, 1083.
Tetrabenzyltrimethylenetrisulphone, 592.
Tetracetyleuxanthic acid, 1354.
Tetracetylhydrindigotin, 480.
Tetracetylpenterythritol, 128.
Tetradecylacetylene, 1163.
Tetradymite from Zsupkó and from Rézbánya, 1054.

Tetrahydrobenzylidene-2 : 6-lutidine, 1361.
Tetrahydroketoquinoxalines, 886.
Tetrahydro-2-methylpyridine, Δ^2, 1243.
Tetrahydro-α-naphthoic acid, 192.
Tetrahydro-β-naphthoic acid, 194.
Tetrahydronaphthylanisoïl, 1445.
Tetrahydronaphthylphenol, 1445.
Tetrahydrophthalic acid, cisΔ^4-, 1216.
Tetrahydropicoline, Δ^2-, 1243.
Tetrahydropinene, 998.
Tetrahydropyrazine, 633.
Tetrahydropyridine, 1484.
Tetrahydropyridine-derivatives, synthesis of, and conversion of, into piperidine derivatives, 1243.
Tetrahydroquinoline, dinitro-, 726.
—— oxidation of, 1104.
Tetrahydroquinoline-derivatives, oxidation of, 355.
Tetrahydroquinolylcarbamide, 725.
—— dinitro-, 726.
Tetrahydrothioquinazoline, 1496.
Tetrahydroxyaurindicarboxylic acid, 1469.
Tetrahydroxybenzophenone and its derivatives, 1225.
Tetraketohexamethylene hydrate, trichloro-, 835.
—— tetrachloro-, 836.
—— tribromo, 836.
Tetralkylammonium iodides, formation of, 133.
Tetramethylbenzamidobenzophenone, action of nitrous acid on, 185.
Tetramethylbenzidine, metadiamido-, 1222.
Tetramethyldiamidoarsenobenzene, 1321.
Tetramethyldiamidobenzhydrol, condensation of, with xylidine, mesidine, pseudocumidine, isoduridine, and prehnidine, 188.
Tetramethyldiamidodiphenylmethoxymethylquinolylmethane, 190.
Tetramethyldiamidophenylquinolylmethane, 190.
Tetramethylene, derivatives of, TRANS., 36.
—— diethyl glycol, TRANS., 58.
—— ethyl ketone, TRANS., 51.
—— —— —— sodium hydrogen sulphite compound of, TRANS., 53.
—— —— ketoxime, TRANS., 54.
—— methyl ketone, TRANS., 47.
—— —— ketoxime, TRANS., 49.
—— phenyl ketone, TRANS., 59.
—— —— ketoxime, TRANS., 61.
Tetramethylenecarboxylic acid, bromo-, TRANS., 41.
—— —— dissociation constant of, TRANS., 705.
Tetramethylenecarboxylic acid, preparation of, TRANS., 40.
—— acids, melting points of, 1040.
—— chloride, preparation of, TRANS., 41.
Tetramethylenedicarboxylic acid, α-, dissociation constant of, TRANS., 705.
—— acids, 1306.
—— —— thermochemistry of, 1041.
Tetramethylene-ethylcarbinol, TRANS., 54.
Tetramethylene-ethylcarbinyl acetate, TRANS., 56.
Tetramethylenemethylcarbinol, TRANS., 50.
Tetramethylenephenylcarbinol, TRANS., 62.
—— polymeride of, TRANS., 65.
Tetramethylenepropyl bromide, TRANS., 58.
—— iodide, TRANS., 57.
Tetramethylorthophenylenediamine, 1474.
Tetramethyltriamidodiphenylmethoxytolylmethane, 190.
Tetramethyltriamidodiphenyltolylmethanes and their derivatives, 187.
Tetra-β-naphthylcarbamide, dithio-, 166.
Tetraphenylcarbamide, dithio-, 165.
—— thio-, 165.
—— tetraphenylthiodithiosemicarbazide, 1326.
Tetraphenylthiophen, 185.
Tetratolylcarbamide, para-, 1083.
Tetratolyloxamide, para-, 1084.
Tetravinylpyridine, 1483.
Tetrazole, 1009.
Tetrazoleazodimethylaniline, 1299.
Tetrazoleazo-β-naphthylamine, 1299.
Tetrazotic acid, amido-, 1299.
Tetrethylacetone, 1188.
Tetrethyldiamidoarsenobenzene, 1321.
Tetrethyleuxanthic acid, 1354.
Tetrethyltriamidodiphenyltolylmethane, 189.
Tetrethyltrimethylenetrisulphone, 592.
Tetrole-nuclei, constitution of, 302.
Tetrolic acid, 961.
Tetrylenedicarboxylic acetoanhydride, 1307.
—— acetochloranhydride, 1307.
—— acid, symmetrical, 1306.
Thallium and potassium chlorates, solubility of mixed crystals of, 266.
—— chlorochromate, 568.
—— chromate, 567.
—— estimation of, 238.
—— hypophosphate, 403.
—— lowering of the freezing point of cadmium by, TRANS., 903.
—— potassium chromate, 568.

Thallium sesquioxide, 568.
Thallium lead alloy, analyses of, TRANS., 914.
Thaumasite from Kjölland, 1407.
Thermal value of the hydroxyl groups in glycol, 576.
Thermochemistry of bibasic organic acids, 395, 1140.
—— of compounds of chlorine with iodine, 1387.
—— of dibromomalonic acid, 1140.
—— of di-, tri-, tetra-, penta-, and hexa-methylene rings, 1041.
—— of disodium glycol, 421.
—— of guanidine and nitroguanidine, 1142.
—— of hydrazine, 933, 1143.
—— of hydroxylamine, 1143.
—— of malic acid, 260.
—— of monosodium and disodium catechol, 1184. 1185.
—— of monosodium mannitol, 800.
—— of monosodium and disodium resorcinol and quinol, 1185.
—— of persulphuric acid and its salts, 931.
—— of phenol, 1041.
—— of sodium isopropoxide, 674.
—— of sodium pyrogalloi, 1313.
—— of sugars, 931.
—— of tartronic acid, 675.
—— of the carbohydrates and polybasic alcohols and phenols, 763.
—— of the cinnamic acids, 469.
—— of the hydroxybenzenes, 1446.
—— of the oxime of opianic anhydride, 459.
—— of the substitution of radicles in union with carbon and nitrogen respectively, 1141.
Thermodynamical coincidence, law of, and its application to the theory of solution, 557.
Thermodynamics, second law of, and its application to chemical phenomena, 3.
Thermoelectric phenomena at the contact of two electrolytes, 1037.
Thetincarboxylic acids, 1433.
Thiacetic anhydride, 300, 581.
Thiamides, action of ethylenediamine on, 1247.
Thiazole, 313.
—— compounds of, 215.
Thienylisoxazolic acid, 304.
Thienylphenylpyrazole, 304.
Thienylphenylpyrazolic acid, 303.
Thiobiurets, 703.
Thiocarbamates, reactions of, 1318.
Thiocarbamide, silver compounds of, 441; TRANS., 249.
Thiocarbamides, 702.
—— action of ethylene bromide on, 466.
Thiocarbamides, aliphatic, action of oxidising agents on, 292.
—— aromatic, action of thiocarbonyl chloride on, 983.
—— unsymmetrical, action of acetone and bromacetophenone on, 216.
Thiocarbaniltolyloxamethane, 599.
Thiocarbimides, compounds of, with aldehyde-ammonias, TRANS., 509.
Thiocarbonyl-β-dinaphthylthiocarbamide, 984.
Thiocarbonyldiparatolylthiocarbamide, 984.
Thiocarbonylthiocarbanilide, 983.
Thiocyanacetone, 1425, 1426.
—— estimation of, 1426.
Thiodiphenylcarbamic chloride, 164.
Thiohydantoic acid, action of phenylhydrazine on, 966.
Thiole, 312.
Thionessal, 185.
—— substitution products of, 718.
Thionyl chloride and aromatic hydrazones, 1324.
Thiophen mercuric chloride, 828.
—— nitrile, 831.
—— tetrabromo-, oxidation of, 302.
Thiophenaldoximes, 1435.
Thiophenantialdoxime, 1435.
Thiopher chloropnosphine and its derivatives, 966.
Thiophendicarboxylic acid, αβ-, 830.
—— —— bromo-, 831.
Thiophendiethylmethylphosphonium iodide, salts, 966.
Thiophendiethylphosphine, 966.
Thiophenoxychlorophosphine, 966.
Thiophenphosphinic acid, 966
Thiophenphosphinous acid, 966.
Thiosulphate and sulphite, action of iodine on a mixture of, TRANS., 1083.
—— solutions, preservation of, 1514.
Thiosulphates, 12, 1418.
Thiosulphonates, aromatic, 990.
Thiosulphonic acids, aromatic, 478.
Thiosulphuric acid, decomposition of, TRANS., 176.
Thiotolene mercuric chloride, β-, 829.
Thiourea, action of nitrous acid on, TRANS., 525.
—— and ammonium thiocyanate, compound of, 1309.
—— compound of silver bromide with, TRANS., 251.
—— compound of silver chloride with, TRANS., 252.
—— compound of silver cyanide with, TRANS., 253.
—— compound of silver iodide with, TRANS., 253.
—— compound of, with aldehyde-ammonia, TRANS., 510.

Thiourea, compound of, with isovaleraldehyde-ammonia, TRANS., 513.
—— compounds of silver nitrate with, TRANS., 250.
—— compounds of, with aldehyde-ammonias, TRANS., 509.
—— properties of, 1309.
—— silver compounds of, TRANS., 249.
Thioureas, PROC., 1892, 96.
—— substituted, isomerism amongst the, TRANS., 536.
Thorium and uranous sulphates, isomorphous, 571.
Thymol, 1078.
—— refractive power of, at different temperatures, TRANS., 305.
Thymolglycuronic acid, 1116.
Tiglic acid, constitution of, 1304.
Tilias, oil from the seeds of, 92.
Tin, action of nitric acid on, 1402.
—— and sodium, alloy of, 572.
—— antimony, and arsenic, detection of, 918.
—— —— —— separation of, TRANS., 424.
—— bismuth, cadmium, and lead, separation of, 754.
—— cadmium, and gold, estimation of, in alloys, 1030.
—— double halogen salts of, 785.
—— estimation of, 1129.
—— lowering of the freezing point of bismuth by, TRANS., 896.
—— lowering of the freezing point of cadmium by, TRANS., 901.
—— lowering of the freezing point of lead by, TRANS., 908.
Tin. See also Stannic.
Tin-ores, analysis of, 540.
Tirmania africana, analysis of, 654.
Tissue, retiform, 1113.
Tissue-fibrinogens, 646.
Titanic oxide, distribution of, on the earth, 791.
Titaniferous iron ore from the Fichtelgebirge, 1406.
Titanium, decomposition of minerals containing, 664.
—— estimation of, in titanium-aluminium, 1131.
—— sesquioxide, action of nitric oxide on, 1152.
Tolallyl sulphide, 185.
Tolane sulphide, 185.
Tolenylamidine nitrite, para-, 53.
Tolidine, metamidortho-, 852.
—— metanitrortho-, 852.
—— polymethylene bases from, 1223.
Tolidinedisulphonamide, 1468.
Tolidinedisulphonic acid, ortho-, 1466.
Tolidinesulphonic acid, 1467.
Tolualanine, nitro-, 1359.
Toluamide, imidodiortho-, 712.
—— imidodipara-, 712.
Toluene, bromination of, TRANS., 1025.
—— diamido-, action of formaldehyde on, 1496.
—— interaction of bromine and, TRANS., 1023.
—— 1 : 2 : 5-dichloro-, sulphonation of, TRANS., 1050.
—— 1 : 3 : 4-dichloro-, sulphonation of, TRANS., 1060.
—— metachloro-, sulphonation of, TRANS., 1075.
—— orthobromo-, bromination of, TRANS., 1031.
—— orthochloro-, sulphonation of, TRANS., 1072.
—— orthonitro-, action of chlorine on, in presence of sulphur, 1437.
—— parabromo-, bromination of, TRANS., 1032.
—— parachloro-, sulphonation of, TRANS., 1078.
—— paramidorthochloro-, 445.
—— refractive power of, at different temperatures, TRANS., 297.
—— 1 : 3 : 4 : 5-trichloro-, TRANS., 1070.
Tolueneazocyanocamphors, ortho- and para-, 1343.
Toluenediazoacetotoluidide, 459.
Toluenehydrazoparacresol, para-, 974.
Toluenemetasulphonic acid, orthometadibromo-, TRANS., 1038.
Toluneparasulphonic acid, bromination of the potassium salts of, TRANS., 1027.
Toluenes, ortho- and para-bromo-, preparation and properties of, TRANS., 1026, 1027.
Toluenesulphonic acid, 1 : 2 : 5-dichloro-, derivatives of, TRANS., 1051.
—— —— 1 : 3 : 4-dichloro-, derivatives of, TRANS., 1061.
—— —— —— hydrolysis of, TRANS., 1068.
—— —— metachloro-, TRANS., 1075.
—— —— ortho-, 1 : 2 : 5-orthobromo-, TRANS., 1041.
—— —— —— 1 : 2 : 5-orthochloro-, TRANS., 1040.
—— —— orthochloro-, TRANS., 1072.
—— acids, mono-, di-, and tri-chloro-, TRANS., 1042.
—— —— ortho- and para-bromo-, TRANS., 1023.
—— —— parachloro-, TRANS., 1078.
Toluenethiosulphonic acid, reactions of, 478.
Toluic acid, meta-, parachloro-, 1201.
Toluic acid, ortho-, parabrom-, nitration and bromination of, 1207.
Toluic acid, para-, 5 : 2-amidochloro-para-, 172.

Toluic acid, para-, 6 : 3-amidochloro-, 173.
—— —— —— 2 : 3-azimido-, 177.
—— —— —— 5 : 2-bromochloro-, 173.
—— —— —— 2 : 3-diamido-, 176.
—— —— —— 2 : 5-diamido-, 176.
—— —— —— 3 : 5-diamido-, 177.
—— —— —— 2 : 3-dibromo-, 175.
—— —— —— 2 : 6-dibromo-, 175.
—— —— —— 3 : 5-dibromo-, 176.
—— —— —— 2 : 3-dinitro-, 176.
—— —— —— 2 : 5-dinitro-, 176.
—— —— —— 2 : 6-dinitro-, 177.
—— —— —— 3 : 5-dinitro-, 177.
—— —— —— metachloro-, nitration of, 173.
—— —— —— 2 : 5-nitramido-, 177.
—— —— —— 3 : 5-nitramido-, 178.
—— —— —— 2 : 5-nitrobromo-, 178.
—— —— —— 3 : 2-nitrobromo-, 175.
—— —— —— 3 : 5-nitrobromo-, 178.
—— —— —— 5 : 2-nitrobromo-, 174.
—— —— —— 6 : 2-nitrobromo-, 175.
—— —— —— 2 : 3-nitrochloro-, 174.
—— —— —— 3 : 2-nitrochloro-, 173.
—— —— —— 5 : 3-nitrochloro-, 174.
—— —— —— orthobromo-, nitration of, 175.
—— —— —— orthochloro-, nitration of, 172.
—— —— —— orthonitro-, nitration of, 176.
Toluic acid, 4 : 1 : 3-sulphamido-, 1092.
Toluic acids, dibromortho-, 1207, 1208.
—— —— nitrobromortho-, 1207.
—— sulphinide, 1092.
Toluidine, commercial, assay of, 925.
Toluidine, meta-, parachloro-, 1201.
Toluidine, ortho-, action of benzyl chloride on, 48.
—— —— and furfuraldehyde, condensation of, 1452.
—— —— chloro-, conversion of, into chlorotoluene, Trans., 1047.
—— —— —— conversion of, into dichlorotoluene, Trans., 1049.
—— —— hydrogen diaminechromium thiocyanate, 1000.
—— —— influence of nucleal methyl on the properties of, 1319.
Toluidine, para-, chloro-, conversion of, into chlorotoluene, Trans., 1058.
—— —— 5 : 2-nitrobromo-, 174.
—— —— 2 : 5-nitrochloro-, 172.
—— —— 6 : 2-nitrochloro-, 172.
—— —— 6 : 3-nitrochloro-, 173.
Toluidineazo-α-naphthol, ethyl and methyl ethers of, 863.
Toluidinemetasulphonic acid, ortho-, metabrom-, Trans., 1037.
Toluidines, ortho- and para-, action of benzyl chloride on, 313.
Toluidinesulphonic acid, ortho-, Nevile and Winther's, constitution of, Trans., 1036.
Toluidobutyric acid, α-ortho-, 1338.
Toluidobutyric acid, α-para-, 1338.
Toluidocinnoline, para-, 1494.
Toluidoisobutyric acid, α-ortho-, 1339.
Toluidoisobutyric acid, α-para-, 1339.
Toluidoisobutyric acid, β-para-, 1339.
Toluidoisobutyric acids, 1339.
Toluidopropionic acid, α-para-, 1337.
Toluidopropionic acid, β-para-, 1343.
Toluonitrile, ortho-, dibrom-, 1208.
Toluonitrile, para-, 2 : 6-dibromo-, 175.
—— —— 3 : 5-dibromo-, 176.
—— —— 2 : 6-dinitro-, 177.
—— —— 6 : 2-nitrobromo-, 175.
—— —— 5 : 2-nitrochloro-, 172.
—— —— 6 : 3-nitrochloro-, 173.
Toluyl methyl ketone, parabromometa-, 338.
Toluyldithiocarbamic acids, salts of, 56.
Toluylenaldehydenitrodimethoxybenzenylorthocarboxylic acid, 1249.
Toluylenediamine, ortho-, derivatives of, 709.
Toluyleneoxamide, 1208.
Toluylenephthalamidone, 1248.
Toluylxylide, ortho-, 491.
Tolyl cyanate, nitro-, 833.
—— isocyanide, ortho-, 1441.
—— —— para-, 1442.
—— methyl ketone, parabromometa-, 1200.
—— —— —— parachlorometa-, 1201.
—— —— ketoxime, parabromometa-, 1201.
—— —— —— parachlorometa-, 1201.
—— orthotolylcarbamate, ortho-, 832.
Tolyl-β-alanine, para-, 1343.
Tolylazimidobenzene, amidopara-, 1322.
Tolylazoparatolylthiobiazolone, para-, 512.
Tolylazoparatolyl-ψ-thiobiazolone, para-, 512.
Tolylazorthotolyldithiobiazolone, ortho-, 513.
Tolylazorthotolylthiobiazolone, ortho-, 513.
Tolylbenzenemetacarboxylic acid, meta-, 851.
Tolylcarbamide, para-, and its derivatives, 460.
Tolyldibenzylcarbamide, para-, 1083.
Tolyldifurylnaphthodihydroquinoxaline, 1476.
Tolyldimethylthiohydantoïn, ortho-, 150.
Tolyldimethylthiohydantoïn, para-, 150.
Tolyl-β-dimethyl-μ-thiomethylimidazole, ν-ortho-, 153.
Tolyl-β-dimethyl-μ-thiomethylimidazole, ν-para-, 153.

Tolyldiphenylethohydronaphthazonium hydroxide, 1474.
Tolyldiphenylnaphthodihydroquinoxaline, 1474.
Tolylenedioxamethane, 603.
Tolylenedioxamic acid, 604.
Tolylenedioxamide, 603.
Tolylenemalonamide, 600.
Tolyleneoxamide, 599.
Tolylfurfurylcarbamide, ortho-, 43.
Tolylfurfurylthiocarbamide, 43.
Tolylglycocine, ortho-, derivatives of, 1333.
Tolylglycocine, para-, 1335.
—— —— and its derivatives, 1335.
Tolylhydantoïn, γ-para-, 828.
Tolylhydrazine phosphenite, para-, 1325.
Tolylhydrazinecamphoric acid, para-, 1481.
Tolylhydrazone, thionylpara-, 1324.
Tolylhydrazoparatolylthiobiazolone, para-, 512.
Tolylhydrazotolyldithiobiazolone, para-, 512.
Tolylhydroxypyrimidinecarboxylic acid, para-, 1008.
Tolylimidocarbonyl chloride, 1441.
Tolylimidodiacetamide, ortho-, 1335.
Tolylimidodiacetic acid, para-, 1336.
—— ditoluidide, para-, 1336.
Tolylimidodiacetimide, ortho-, 1335.
Tolylimidazole, ν-para-, 1329.
Tolylimidazolyl methyl sulphide, 1329.
Tolylimidazolyl-μ-mercaptan, ν-para-, 1328.
Tolylisoquinoline, β-para-, 475.
—— —— α-chloro-, 474.
Tolyl-β-methyl-α-methoxy-μ-thiomethylimidazole, ν-ortho-, 152.
Tolyl-β-methyl-α-methoxy-μ-thiomethylimidazole, ν-para-, 152.
Tolyl-α-methylphthalimide, para-, 608.
Tolylmethylthiohydantoïn, ortho-, 150.
Tolylnaphthylenediamine, 1476.
Tolylorthazodibenzylamine, para-, 316, 890.
Tolylorthonaphthylenediamine, para-, and its anhydro- and thio-derivatives, 1473.
Tolylorthotolylsemithiocarbazide, para-, Trans., 1016.
Tolyloxamethane, amido-, 599.
—— nitro-, 601.
Tolyloxamic acid, amido-, 599, 601, 1208.
—— —— urethano-, 599, 1208.
Tolyloxamide, amido-, 602.
—— nitro-, 601.
Tolyloxanilide, amido-, 602.
Tolylparatolylsemithiocarbazide, ortho-, Trans., 1015.
Tolylphenylacetonitrile, 1094.
Tolylphenylketoximes, ortho-, 490.
Tolylphenylsemithiocarbazide, para-, Trans., 1013.
Tolylphthalimide, ortho-, preparation of, 1204.
Tolyltetrahydroketoquinazoline, para-, 1496.
Tolyltetrahydrothioquinazoline, 1496.
Tolylthiocarbazinic orthotolylhydrazide, ortho-, 513.
Tolylthiocarbazinic paratolylhydrazide, para-, 511.
Tolylthiocarbimide-aldehyde-ammonia, ortho-, Trans., 520.
Tolylthiohydantoïn, ortho-, 150.
Tolylurethane, amido-, 600, 1203.
—— paramido-, 601.
—— paranitro-, 601.
Tomato, cooked, composition of, Trans., 227.
Tourmaline, formula of, 1410.
—— red, from Siberia, 573.
Toxic action of blood and various tissues, 228.
Toxic principles of *Amanita pantherina*, 232.
Toxicity of serum, 228.
Transpiration, 1267.
Transportation of solids in a vacuum by the vapours of metals, 1386.
Trees, occurrence of calcium oxalate in the bark of, 1370.
Trehalose, detection and extraction of, 545.
—— thermochemistry of, 764.
Triacetic acid, lactone of, preparation of pyridine derivatives from, Trans., 721.
Triacetin, 289.
Triacetylglycerol, 289.
Triammonium imidosulphonate, anhydrous, Trans., 949.
—— —— hydrated, Trans., 948.
Triargentic imidosulphonate, Trans., 974.
Triazobenzene, physiological action of, 366.
Triazole, 735.
Triazolecarboxylic acid, 735.
Triazole-derivatives, 637.
Triazoles, nomenclature of, 889.
Tribenzyl orthothioacetate, 612.
Tribenzylcarbamide, 1083.
Tribenzylpyridine, 1365.
Tribenzylsulphonemethylmethane, 613.
Tribenzylsulphonephenylmethane, 613.
Tribromhydrin, symmetrical, formation of, 577.
Tricalcium phosphate, action of carbonic anydride and of ferric hydroxide on, 408.
—— —— solubility of, in solutions of phosphoric acid, 684.

Tricarballylic acid, dissociation constant of, TRANS., 707.
Tricinnamtetra-ureïde, 57.
Tricyanides, formation of, from nitriles and acid chlorides, 1183.
Triethoxytriphenodioxazine, 158.
Triethyl orthothioacetate, 612.
Triethylamine platinothiocyanate, 286.
Triethylgallic acid, amido-, 716.
—— —— dibromo-, 715.
—— —— nitro-, 716.
Triethylidenecinchonine, 1252.
Triethylpyrogallol, amido-, 716.
—— nitro-, 716.
Triethylresorcinol, action of nitrous acid on, 44.
Triethylsulphonemethylmethane, 154.
Trifolium, analyses of, 522.
Trihydroxyaurindicarboxylic acid, 1469.
Trihydroxybenzophenone, bromo-, 1225.
—— derivatives of, 1224.
—— nitro-derivatives of, 1225.
—— sodio-, 1224.
Trihydroxyglutaric acid, second inactive, 437.
Trihydroxyquinoxaline, 734.
Trihydroxystearic acids prepared from ricinoleïc and ricinelaïdic acids, stereochemistry of, 1304.
Triketopentamethylene hydrate, dibromo-, 836.
—— tribromo-, 836.
—— trichloro-, 835.
Trimethylacetaldehyde, 39.
Trimethylacetic acid, solubility of salts of, 581.
Trimethylallylammonium iodide, 1295.
Trimethylamine, action of capryl iodide on, 806.
—— action of isoamyl iodide on, 805.
—— action of isobutyl iodide on, 805.
—— chloriodide, 1357.
—— ethylene bromide, 806.
—— —— iodide, 808.
—— hydrogen diaminechromium thiocyanate, 1000.
—— physiological action of, 366.
—— platinocyanate, 286.
—— pure, preparation of, 805.
Trimethylbenzaldehyde, 329.
Trimethylcarbinol, action of bromine on, 809.
—— sodio-, 1066.
Trimethylchlorethylammonium platinochloride, 807.
Trimethyldiamidobenzophenone, 185.
—— nitrosamine of, 185.
Trimethyldihydroquinoline, 614.
Trimethyldihydroxyethylammonium salts, 807.
Trimethylene chlorobromide, action of aromatic amines and amides on, 1491.
Trimethylene, constitution of, 1163.
—— iodide, preparation of, 1062.
Trimethylenedicarboxylic acids, melting points of, 1040.
Trimethylenedisulphonesulphide, 592.
—— di-, and hexabromo-, 593.
Trimethylenepolycarboxylic acids, thermochemistry of, 1041.
Trimethylenetetracarboxylic acid [1, 1, 2, 2], 1040.
Trimethylenetrisulphone, 591.
—— hexabromo- and tetrachloro-, 592.
Trimethylethylidenelactic acid, β-, 38.
Trimethylfurfurylammonium iodide, 43.
Trimethylgallic acid, nitration of, 716.
Trimethylisopropylammonium iodide, 1295.
Trimethylpropylammonium iodide, 1294.
Trimethylsulphine iodide, 300.
—— preparation of, 1422.
Trimethylthiohydantoïn, 151.
Trimethyl-μ-thiomethylimidazole, νβ-, 153.
Trimethylvinylammonium salts, 806.
Triphenyl orthothioacetate, 612.
Triphenylbenzene, symmetrical synthesis of, 993.
Triphenylcarbamide, thio-, 164.
Triphenylethophenazonium hydroxide, amido-, 1109.
Triphenylguanidine picrate, 950.
Triphenyl-γ-hydroxypropylideneacetethylamide, αβδ-, 485.
Triphenyl-γ-hydroxypropylideneacetic acid, αβδ-, 484.
Triphenylisotriazone, 1471.
Triphenylmethane and chloroform, condensation of, 722.
—— preparation of, 719.
Triphenylmethane-group, dyes of the, 187.
Triphenyl-β-naphthylcarbamide, 167.
—— thio-, 165.
Triphenylpyrrolone, 1003.
Triphenylsulphonebromomethane, 611.
Triphenylsulphonechloromethane, 611.
Triphenylsulphonemethylmethane, 612.
Triphenyltetrahydropyrazine, 634.
Triplite from South Dakota, 1406.
Trisodium imidosulphonate, TRANS., 958.
Trisulphones, 153.
—— formation of, from disulphones, 613, 850.
Trithionate, formation of, by the action of iodine on a mixture of sulphite and thiosulphate, PROC., 1892, 91.
Tritolylcarbamide, para-, 1083.
Tropeïnes, ψ-, 891.
Tropine, 358.
—— action of hypochlorous acid on, 1014.

Tropine, constitution of, 1244.
Tropine, ψ-, 891.
—— atropate, 892.
Tropyl-ψ-tropeïne, 891.
Truffles of Europe, relation between the terfâs or kamés of Africa and Western Asia and the, 654.
Tscheffkinite, analysis of, 23.
Tubes, block support for, 9.
Tungsten dioxide, action of nitric oxide on, 1152.
—— electrolytic separation of gold from, 920.
—— estimation of, in rich alloys and in steel, 539.
Tungstic acid, action of hydrogen peroxide, on, 944.
—— —— estimation of, 241.
Turkey-red oil, 819.
Turnips, cooked, composition of, TRANS., 227.
Turpentine, action of benzoic acid on, 199.
—— behaviour of, in mixtures of two solvents, 1137.
—— constitution of, 864.
—— detection of, in essences, 386.
—— reaction of, with manganous salts, 386.

U.

Ullmannite from Siegen, 124.
Unsaturated aromatic compounds, action of nitrous acid on, 1198.
Uramidotolyloxamethane, 603.
Uramidotolyloxamic acid, 602.
Uramidotolyloxamide, 603.
Uraninite, new analyses of, 283.
Uranium oxide, action of nitric oxide on, 1152.
Uranous and thorium sulphates, isomorphous, 571.
Urea, cryoscopy of dilute solutions of, 1045.
—— excretion of, 365.
—— mechanism of the production of, in the animal organism, 89.
—— oxalate, 1421.
Urea. See also Carbamide.
Urethanotolyloxamethane, 601.
Urethanotolyloxamic acid, 602.
Urethanotolyloxamide, 601.
Uric acid, estimation of, 546, 1032, 1133.
—— —— excretion of, 365.
—— —— formation of, from cyanacetic acid and carbamide, 149.
—— —— formation of, from nucleïn, 646.
—— —— formation of, in the blood of mammals, 1257.
Uric acid, influence of hot baths on the excretion of, from the human system, 1503.
Uric acid-group, azines of, 70.
Urine, carbonic anhydride in, 649.
—— detection of albumin in, 667, 928.
—— detection of hæmatoporphyrin in, 1136.
—— detection of quinine and phenacetin in, 665.
—— estimation of creatinine in, 1135.
—— estimation of gallic acid in, 924.
—— estimation of homogentisic acid in, 925.
—— ethereal hydrogen sulphates in, 226.
—— excretion of nitrogen in, 1503.
—— hæmatoporphyrin in, 649.
—— human, estimation of phenols in, 544.
—— —— normal, reducing agents in, 1504.
—— —— putrefying, carbohydrates of, 226.
—— in a case of phosphorus poisoning, 650.
—— of animals, occurrence of acetyl derivatives in, after the ingestion of aldehydes, 1504.
—— of hydrophobic rabbits, catechol in, 1115.
—— phosphoric acid in, 1115.
—— sulphates and ethereal hydrogen sulphates in, during diarrhœa, 1505.
—— volumetric estimation of peptones in, 1264.
—— volumetric estimation of sulphuric acid in, 1377.
—— xanthocreatinine in the, 364.
Urohæmatoporphyrin, 744.
Uvic acid, preparation of, 814.

V.

Vacuum, transportation of solids in, by the vapours of metals, 1386.
Valeraldehyde, δ-amido-, 1484.
Valeraldehydeaniline, 1193.
Valeric acid, dibromo-, decomposition of, 960.
Valerolactone, bromo-, 960.
—— hydrolysis of, 1303.
Vanadic acid, action of hydrogen peroxide on, 944.
Vanillenylamidoxime, 318.
Vanillonitrile, 318.
Vanilloylcarboxylic acid, 64.
Vaporisation, heat of, of a solution, 1382.
Vapour densities, determination of, under reduced pressure, 553.
—— density, determinations of, 934.

Vapour pressure, apparatus for the indirect determination of, 679.
—— —— of aqueous solutions of cobalt chloride, 263.
—— —— of water, 396.
—— pressures of solutions, measurement of, TRANS., 769.
Vapour tension of homologous compounds, 396.
Vapours, saturated, of various liquids under the same pressure, temperatures of, 1143.
—— —— pressure and specific volume of, 263.
Vegetable amyloïd, 803.
Vegetable marrow, cooked, composition of, TRANS., 227.
Vegetables, cooked, composition of, TRANS., 226.
—— estimation of pentoses in, 247.
Vegetation, fixation of free nitrogen during, 1508.
—— influence of the nature of the soil on, 1121.
—— of the vine, 908.
—— rain as a source of nitrogen for, 233.
Velocities, relative, of the action of iodine on a mixture of sulphite and thiosulphate, TRANS., 1036.
Velocity of decomposition of diazo-compounds by water, 768.
—— of reaction between alcoholic potash and alkyl halides, 399.
—— —— in mixtures of isohydric and non-isohydric solutions of acids, 936.
Veratroïl, dinitro-, 180.
Vermiculites, constitution of, 125.
Vesuvian from Norway, 1408.
Vicia, analyses of, 522.
Vine, origin of the colouring matter of, 1242.
—— vegetation of, 908.
Vinegar, examination of, 251.
Vinyltrimethylammonium salts, bromo-, 807.
Viscosity of aqueous salt solutions, 1044.
—— of liquids, 1143.
Vitoglycol, 746.
Vitole, 746.
Vivianite from Tamanj, 690.
Volume, E.M.F., and temperature, changes of, on mixing electrolytes, 930.
—— lag, and its bearing on molecular constitution, 1043.
Volumes, Gay Lussac's law of, 1271.
—— molecular, of dissolved substances, 1383.
—— of liquid and gaseous mixtures, 935.
Volumes. See also Specific volumes, Molecular volumes.
Volumeter, gas-, PROC., 1891, 171.

W.

Water of the lakes of Aiguebelette, Paladru, Nantua, and Sylans, 1061.
Water, composition of, 1271.
—— estimation of dissolved substances in, 920.
—— estimation of fixed and volatile organic matter in, 921.
—— estimation of nitrates in, 243.
—— estimation of oxygen dissolved in, 98; TRANS., 310.
—— expansion of, by heat, 7, 106, 1382.
—— extraction of the dissolved gases in, 1526.
—— from the Arctic Ocean, 1287.
—— influence of, on nitrogenous excretion, 904.
—— influence of temperature on Griess' reaction for nitrites in, 657.
—— maximum density of, 7.
—— mineral, at Sclafani, 25.
—— —— of Monte di Malo, 1287.
—— of crystallisation, 581.
—— rain, ammonia in, 381, 909.
—— refractive power of, at different temperatures, TRANS., 293.
—— solubility of gases in, 107.
—— vapour, saturated, pressure of, 396.
Water-gas, action of, on iron, PROC., 1891, 126.
Water-generator gas, reconversion of heat into chemical energy by production of, 673.
Waters, mineral, alteration of chalybeate, 1288, 1289.
—— —— aluminium in, 1287.
—— —— at Eilsen, 796.
—— —— preservation of, 1162.
—— natural, colour standard for, 1527.
—— of the North Sea on the coasts of Holland, 419.
—— subterranean, near Port-Vendres, 285.
Wax, detection of resin in, 923.
—— Japan, sp. gr. of, 428.
—— vegetable, assay of bees'-wax for, 551.
—— white, analysis of, 665.
Weighing, rapid, modified balance for, 270.
Weight, live-, influence of various salts on, 647.
Wheat, growth of, in a sterile siliceous soil, 909.
—— proteïds and carbohydrates in, 1119.
Willemite from New Jersey, 1411.
Wine, estimation of glycerol in, 1529.
—— estimation of glycerol, astringent acids, and colouring matter in, 246.

Wine, estimation of potato-starch sugar in, 922.
—— influence of, on peptic digestion, 87.
—— plastered, behaviour of strontium tartrate with, 93.
—— presence of boric acid in, 93.
Wine-lees, estimation of cream of tartar in, 1033.
Wines, decolorisation of, 543.
—— detection of alum in, 1523.
—— sweet, estimation of glycerol in, 1263.
—— —— estimation of tartar in, 1531.
Wolfsbergite from the Harz, 124.
Wollastonite from Perheniemi, Finland, 1407.
Wood, ketones obtained in the dry distillation of, 424.
—— sulphite liquor, 802.
Woollen tissue, detection of vegetable fibre in, 667.

X.

Xanthine, presence of, in the horse's liver, 516.
—— reaction of, 1534.
Xanthocreatinine in the urine, 364.
Xanthones of the naphthalene and quinoline series, 1098.
Xylaldiphenylmaleïde, para-, 482.
Xylalphthalide, para-, 473.
—— —— nitro-derivatives of, 474.
Xylalphthalimidine, para-, 474.
Xylene, meta-, bromonitro-, 1437.
—— —— chloronitro-, 1437.
—— —— cyanonitro-, 1437.
—— —— derivatives of, 1437.
—— —— fluoro-, 968.
—— —— fluoronitro-, 1437.
—— —— iodonitro-, 1437.
Xylenediazopiperidide, nitrometa-, 1437.
Xylenedisulphonic acid, meta-, 1340.
Xylenedisulphonic acid, ortho-, 1341.
Xylenedisulphonic acids, 1340.
Xylenes, action of aluminium chloride on, 1309.
—— separation of the, 1134.
Xylenesulphonic acids, meta-, Proc., 1891, 189.
Xylidine, meta-, action of benzyl chloride on, 314.
—— —— unsymmetrical, action of benzyl chloride on, 1320.
Xylidine, ortho-, chlor-, 1202.
Xylidine zinc chloride, 1455.
Xylitol, 28.
—— constitution of, 29.
Xylitol pentanitrate, 29.
Xylose, 28.
—— constitution of, 29.
—— disappearance of the multirotation of, in ammoniacal solution, 1419.
—— gum in plants which on saccharification yield, 380, 1371.
—— optical properties of, 1420.
—— physiological action of, 1506.
—— reactions of, 290.
—— thermochemistry of, 763.
Xylyl methyl ketone, bromopara-, 338.
—— —— —— 3-chloro-1 : 2-, 1202.
—— —— —— parachlorometa-, 1 : 2-, 1201.
—— orthotolyl ketone, 491.
Xylylic acid, nitrometa-, 1437.
Xylylfurfurylcarbamide, meta-, 43.
Xylylfurfurylthiocarbamide, meta-, 43.
Xylylimidazole, ν-meta-, 1330.
Xylylimidazolyl-μ-mercaptan, ν-meta-, 1329.
Xylylimidazolyl-μ-methyl sulphide, ν-meta-, 1330.
Xylylmethylthiohydantoïn [1 : 3 : 4-], 150.
Xylylphenylketoximes, 490, 491.
Xylylphenylpropionic acid, 849.
Xylylphthalimidine, para-, 474.

Y.

Yeast, hydrolytic functions of, Trans., 593, 926.
—— velocity of the hydrolytic action of, Trans., 928.
—— purification of, 905.
Yeast-cells, effects of varying environment on, Trans., 369.
Yolk of eggs, estimation of fat in, 1134.
Yttrium earth, 1400.

Z.

Zeïn, 749.
Zinc, action of chlorine and of bromine on, 118.
—— action of nitric acid on, 1279.
—— action of, on chromic fluoride, 20.
—— ammonionitrosonaphtholsulphonate, 346.
—— and manganese, separation of, 385.
—— bromide, boiling point of, 680.
—— chloride, boiling point of, 680.
—— cyanide, formation of, from zinc dust, 1164.
—— estimation of, 1129.
—— estimation of, by the ferrocyanide process, 915.
—— fluorovanadite, 788.

Zinc, fluoroxyhypovanadate, 787.
—— fluoroxyvanadate, 787.
—— hydrosulphide, TRANS., 130.
—— lead, and silver, separation of, in galena and blende, 1378.
—— lowering of the freezing point of bismuth by, TRANS., 893.
—— lowering of the freezing point of cadmium by, TRANS., 899.
—— lowering of the freezing point of lead by, TRANS., 905.
—— mercuric cyanide, TRANS., 666.
—— —— thiocyanate, 10.
Zinc nitrates, basic, 1156.
—— orthoborate, 404.
—— oxide, action of hydrogen peroxide on, 1278
—— separation of manganese from, 537.
—— sulphate, crystallised anhydrous, 941.
—— volumetric estimation of, 534.
Zirconium chloride, preparation of, from zircons, 412.
Zoïsite from Orenburg, 690.
